A 10x10 grid of 100 small images showing various stages of a plant's growth, from a seedling to a mature plant. The images are arranged in a grid, with the first row showing the earliest stages and the last row showing the most advanced stages. The plants are shown in various colors, including green, yellow, and brown, and are set against a black background.

INTRODUCTION

The Air Force Office of Scientific Research Technical Report Summaries are published quarterly as of March, June, September, and December of each calendar year. They consist of a brief summary of each AFOSR technical report received in the Technical Information Division and submitted to the Defense Technical Information Center (DTIC) for that quarter. The summaries contain two indexes for easily locating the technical reports that may be of interest to the user. These are followed by abstracts of the reports.

1) SUBJECT INDEX

- a. Subject Field
- b. Title of Report
- c. AD Number (Accession Number)

2) PERSONAL AUTHOR INDEX

- a. Primary Author
- b. Title of Report
- c. AD Number

AFOSR does not maintain copies of technical reports for distribution. However, you may obtain any of these reports if you are a registered government agency or government contractor with DTIC, by requesting the AD number of that report from the DTIC, Cameron Station, Alexandria, Virginia, 22314.

PURPOSE

The purpose of this report is to inform Air Force Laboratories about the science that the Air Force Office of Scientific Research is supporting.

AFOSR MISSION

The Air Force Office of Scientific Research (AFOSR) is the Single Manager of the Air Force Defense Research Sciences Program (Program Element 61102F) and the primary Air Force agency for the extramural support of fundamental scientific research. The AFOSR is organizationally under the DCS/Science and Technology, Air Force Systems Command.

AFOSR awards grants and contracts for research in areas of science relevant to the needs of the Air Force. Research is selected for support from proposals received in response to the Broad Agency Announcement originating from scientists investigating problems involving the search for new knowledge and the expansion of scientific principles. Selection is on the basis of scientific potential for improving Air Force operational capabilities, originality, significance to science, the qualification of the principal investigators, and the reasonableness of the proposed budget.

KEY TO READING THE DATA

The summaries consist of two indexes and the abstracts. From one of the two indexes, locate the AD number of the report that is of interest to you. Use this number to locate the abstract of the report in the abstracts section. The first report submitted to DTIC during the quarter (the one with the lowest AD number) appears on the last page of the abstracts section. The last report submitted to DTIC during the quarter (the one with the highest DTIC number) appears on the first page of the abstracts section. The following terms will give you a brief description of the elements used in each summary of this report.

DTIC Report Bibliography - DTIC's brief description of a technical report.

Search Control Number - A number assigned by DTIC at the time a bibliography is printed.

AD Number - A number assigned to each technical report when received by the DTIC.

Field & Group Numbers - (appearing after the AD number) First number is the subject field and the second number after the slash is the particular group under that subject field.

Corporate Author/Performing Organization - The organization; e.g., college/university, company, etc., at which the research is conducted.

Title - The title of the technical report.

Descriptive Note - Gives the type of report; e.g., final, interim, etc., and the period of the time of the research.

Date - Date of the technical report.

Pages - Total number of pages contained in the technical report.

Personal Author - Person or persons who wrote the report.

Contract/Grant Number - The instrument control number identifying the contracting activity and funding year under which the research is initiated.

Project Number - A number unique to a particular area of science; e.g., 2304 is the project number for mathematics.

Task Number - An alphanumeric number unique to a specific field of the main area of science; e.g., 2304 is the project number for mathematics and A3 is the task number for computational sciences.

Monitor Number - The number assigned to a particular report by the government agency monitoring the research. The number consists of the government monitor acronym, the present calendar year and the technical report assigned consecutively; e.g., AFOSR-TR-83-0001 is the first number used for the first technical report processed for Calendar Year 1983.

Supplementary Note - A variety of statements pertaining to a report. For example, if the report is a journal article, the supplementary note might give you the journal citation, which will include the name of the journal the article it appears in, and the volume number, date, and the page numbers of the journal.

Abstract - A brief summary describing the research of the report.

Descriptors - Key words describing the research.

Identifiers - Commonly used designators, such as names of equipment, names of projects or acronyms, the AFOSR project and task number, and the Air Force Research Program Element number.

UNCLASSIFIED REPORT

ABSTRACT: (U) Proposed was the purchase of a Molecular Beam Epitaxy (MBE) system as the key instrument to establish a coherent, interdisciplinary research program in the area of quantum well structure research. The system will have two growth chambers instead of the proposed single chamber. One is a conventional solid source MBE system and the other is the novel gas source MBE with organometallic sources. Our growth capability is thus enhanced by the acquisition of a system in which pioneering materials research can be performed. Custom modifications to the growth systems have been incorporated to allow non-standard, in situ MBE analytical studies to be performed. It is believed that our MBE system is at present unique in a US university. These programs will concentrate on basic material growth kinetics in gas source MBE, heterojunction and multi-quantum well (MQW) electronic and optical properties and devices for integrated optoelectronics.

Letters, v23 p103-106 1986.

ABSTRACT: (U) The satisfiability problem (SAT) is the
problem of determining whether a given collection I of
disjunctions (clauses) of boolean literals can all be
satisfied (have value true) by some consistent assignment
of truth values to the literals of I (truth assignment).
SAT is NP-complete so there is no known efficient
algorithm for solving this problem. The Davis-Putnam
procedure (DPP)(4) is a well-known, much studied method
for solving instances of SAT. The probabilistic analysis
of variants of DPP under the assumption of constant-
density input distributions such as in (7,8,9) has given
the impression that the David-Putnam procedure is
intrinsically a very fast method for solving most
instances of SAT. This impression is moderated somewhat
by the results of this letter which show that the
following two trivial algorithms, run concurrently, solve
'more' instances of SAT in polynomial time than all
previously studies algorithms.

ABSTRACT: (U) The purpose of this paper is to extend
previous results in order to achieve more versatile,
convenient stability criteria for a wide class of finite-
difference approximations to initial-boundary value
problems associated with the hyperbolic system $u_{\text{sub } t} =$
 $Au_{\text{sub } x} + bu + f$ in the quarter plane $x > 0, t > 0$. With
these criteria, stability is easily established for a
large number of examples, where many of the cases studied
in the recent literature are included and generalized.

ABSTRACT: (U) Over the past year, we have made
significant progress in understanding shape perception
based on curvature extrema. Through psychophysical
experiments in conjunction with H.R. Wilson (Univ. of
Chicago), we now are able to identify which of several
computer algorithms for extracting curvature are
biologically the most feasible.

ABSTRACT: (U) The recent accomplishments are reviewed for a research program employing combined analytical-experiments techniques to study the three dimensional characteristics and behavior of vortex motions associated with the turbulence production process in turbulent boundary layers. Progress is described in the development of a new image processing technique which allows the derivation of quantitative data from flow visualization images. The method is used to search for the role of hairpin vortices in the turbulence production process. In the analytical portion of the study, calculations have been carried out to compute the evolution of a hairpin vortex in a shear flow; the interaction of a pair of hairpins has been examined as well as the viscous response at a wall due to the motion of a hairpin vortex. Comparison of these computer simulations with the experimental studies is very encouraging. Computations for the evolving flow between wall layer streaks during a typical cycle in the wall layer of a turbulent boundary layer have also been carried out; these studies show two possible routes to breakdown of the wall layer flow leading to the production process. Keywords: Turbulent boundary layers; Hairpin vortices; Vortex motion.

DESCRIPTORS: (U) *TURBULENT BOUNDARY LAYER, *VORTICES.

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on Automatic Control, VAC-31 n12 p1091-1096 Dec 86.

ABSTRACT: (U) Certain hyperbolic systems of partial differential equations which are known to be uniformly asymptotically stabilizable using point sensors/actuators (S/A) are considered. The issue to be investigated is the effect on stability when point S/A's are replaced by concentrated S/A's, that is, S/A's which average over small regions of the spatial domain. Although it is known that passing from point to concentrated S/A's necessarily destroys uniform stability, a necessary and sufficient condition for strong stability is obtained in terms of the S/A weighting functions. In addition, in the special case of a cantilevered beam controlled by a single sensor/actuator pair concentrated at the free end, another, more robust type of stability is shown to hold, even when strong stability does not. The latter result shows that the system energy is bounded by a part which goes uniformly to zero at infinity and a residual which can be explicitly estimated in terms of the support of the weight functions and the initial energy. Furthermore, the residual energy converges to zero as the support reduces to the point at the point at the free end of the beam.

p807-817 1987.

ABSTRACT: (U) When two pulsed dye lasers are tuned in
spatial and temporal coincidence to two connected atomic
transitions in a flame or plasma, the resonance
fluorescence monitored from the first excited level
decreases due to the depletion of the population of that
level induced by the second laser excitation step. The
monitoring of such a decrease (fluorescence dip) can be
shown from simple theoretical considerations to be useful
for diagnostic studies and for the evaluation of some
fundamental parameters of the atomic transition involved
in the second excitation step. Both steady state and
transient behaviour are discussed. The information
content of the fluorescence dip is similar to that of the
saturated fluorescence signal. However, several distinct
advantages are offered by the new technique especially
when the level reached by the second excitation step is
close to the ionization limit of the atom. Keywords:
Fluorescence, Laser excitation, Flame, Fluorescence dip,
Plasma, Diagnostics.

SUPPLEMENTARY NOTE: Pub. in Faraday Discussions of the
Chemical Society, v82 p13-24 1988.

ABSTRACT: (U) Correlations between either scalar or
vector quantities measured in the study of
photodissociation dynamics can serve to provide a very
detailed picture of the dissociative event. This article
discusses the use of Doppler profile and time of flight
spectroscopy to learn about the correlation between the
separate internal energies of two recoiling fragments, to
study the way in which the internal energy distribution
of a fragment varies with its recoil direction and to
determine the angle between a photofragment's recoil
velocity direction and its rotation vector. Two new
techniques are introduced. High-voltage switching of the
potential applied to a time-of-flight mass spectrometer
is used to map the velocity distribution of
photofragments onto their arrival time distribution.
Probing of photofragments by polarized light with sub-
Doppler resolution is used to determine the degree of
angular correlation between their rotation vector and
their recoil velocity vector. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) This report describes work addressing the problems of collisional induced oscillator strength and energy transfer from metastable states in Group IIA alkaline earth metal atoms. The quenching of CA 3PJ states when perturbed by rare gas atom collisions is investigated and such quenching is found to be negligible. The CA 1D2 state, however shows considerable collisional induced effects. Calculations have been performed which show that collision cross-sections for transfer of electronic excitation may be switched from the low values typically associated with off-resonant processes to the high values associated with resonant processes by using a strong laser to bring dressed states in one atom in and out of resonance with bare states in another atom. Keywords: Slow atomic collisions; Chemical lasers.

UNCLASSIFIED REPORT

ABSTRACT: (U) Passive and active control of jet shear layer development were investigated as mechanisms for modifying the global characteristics of jet flowfields. Slanted and stepped indeterminate origin (I.O.) nozzles were used as passive, geometry-based control devices which modified the flow origins. Active control techniques were also investigated, in which periodic acoustic excitation signals were injected into the I.O. nozzle shear layers. Flow visualization techniques based on a pulsed copper-vapor laser were used in a phase-conditioned image acquisition mode to assemble optically averaged sets of images acquired at known times throughout the repetition cycle of the basic flow oscillation period. Hot wire data were used to verify the effect of the control techniques on the mean and fluctuating flow properties. The flow visualization images were digitally enhanced and processed to show locations of prominent vorticity concentrations. Three-dimensional vortex interaction patterns were assembled in a format suitable for movie mode on a graphic display workstation, showing the evolution of three-dimensional vortex systems in time. Keywords: Fluid mechanics; Shear layers; Jet flows; Passive control; Active control; Image processing; Control of turbulence; Asymmetric nozzles;

UNCLASSIFIED REPORT

ABSTRACT: (U) We consider a stochastic dynamic system which is governed by a multidimensional diffusion process with constant drift and diffusion coefficients. The correction corresponds to an additive input which is under control. There is no limit on the rate of input into the system. The objective is to minimize the expected cumulative cost associated with the position of the system and the amount of control exerted. It is proved that Hamilton-Jacobi-Bellman's equation of the problem has a solution, which corresponds to the optimal cost of the problem. An existence of optimal policy is proved.

UNCLASSIFIED REPORT

ABSTRACT: (U) A sequence of qualitatively robust predictive source encoders, for a Gaussian stationary source with outlier contaminated observation data, is proposed and analyzed. Performance measures include mean difference-sequence distortion and output entropy at the nominal Gaussian source, as well as breakdown point and influence function. The proposed sequence of predictive encoders attains strictly positive breakdown point and uniformly bounded influence function, at the expense of increased mean difference-squared distortion and differential entropy, at the Gaussian nominal source.

ABSTRACT: (U) Our objective is to develop methodology for analyzing life test data. Initially, there is only data-no mathematical models. Through an exploratory data analysis or an analysis based on the physical processes generating the data, an exponential life distribution model may be judged as appropriate for the analysis of the data. Specifically: where λ is the unknown constant failure rate. The vertical bar in $F(x/\lambda)$ indicates that we are conditioning on the parameter λ ; i.e., for specified λ the distribution is exponential with failure rate λ . The corresponding density is $F(x/\lambda) = \lambda \exp -\lambda x$, $x > 0$.

symmetric errors. Our conclusion is that one should iterate so that residuals are based on generalized least squares. Finally, robustness issues are of even more importance here than in estimation of a regression function for the mean. The loss of efficiency of the standard method away from the normal distribution is much more rapid than in the regression problem.

SUPPLEMENTARY NOTE: Revision of report dated Jul 86, AD-A174 981.

ABSTRACT: (U) Heteroscedastic regression models are used in fields including economics, engineering, and the biological and physical sciences. This paper studies variance function estimation in a unified way, focusing on common methods proposed in the statistical and other literature, in order to make both general observations and compare different estimation schemes. There are significant differences in both efficiency and robustness for many common methods. A general theory is developed for variance function estimation, focusing on estimation of the structural parameters and including most methods in common use in our development. The general qualitative conclusions are these. First, most variance function estimation procedures can be looked upon as regressions with responses being transformations of absolute residuals from a preliminary fit or sample standard deviations from replicates at a design point. The former is typically more efficient, but not uniformly so. Secondly, for variance function estimates based on transformations of absolute residuals, we show that efficiency is a monotone function of the efficiency of the fit from which the residuals are formed, at least for

UNCLASSIFIED REPORT

ABSTRACT: (U) A simple linear calibration function can be used over a wide concentration range for the Inductively Coupled Plasma (ICP) spectrometer due to its linear responses. The random errors over wide concentration ranges are not constant, and constant variance regression should not be used to estimate the calibration function. Weighted regression techniques are appropriate if the proper weights can be obtained. Use of the calibration curve to estimate the concentration of one or more unknown samples is straightforward, but confidence interval estimation for multiple use of the calibration curve is less obvious. A method is described for modeling the error along the ICP calibration curve using the estimated parameters from the fitted model to calculate weights for the calibration curve fit. Multiple and single-use confidence interval estimates are obtained and results along the calibration curve are compared.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Jnl. of the Americal Chemical Society, v109 n8 p2449-2456 1987.

ABSTRACT: (U) The photochemistry of methylbenzyl benzyl ketones (ACOB) in the presence of pentasil zeolites follows strikingly different pathways due to the location of the absorbed ketone. The product distribution, in terms of the cage effect (efficiency of geminate radical combination), demonstrates the effects of sorption and diffusion on the radical species produced by photolysis. p-ACOB is readily adsorbed within the pentasil framework and produces p-AB as the primary product. In contrast, the photolysis product distributions of o-ACOB can be dramatically varied depending upon the extent of its adsorption into the framework. By addition of a non-reactive titrant, such as water, after the ketone adsorption, the photolysis product distributions can be systematically varied depending upon the aluminum content of the framework. The observed results are completely described by considerations of (a) the size and shape sorption of the pentasil zeolites, (b) the sorption of water by the hydrophilic sites of the pentasil zeolites (which depend upon the framework aluminum content), and (c) the hydrophobic characteristics of pentasil channels which do not contain framework aluminum. Keywords: Zeolites; Pentasil; Molecular sieves; Cage effects;

ABSTRACT: (U) Since October 1983, a new HF radar
facility has been operated from Goose Bay, Labrador, for
the purpose of studying high-latitude ionospheric
irregularities. This paper, presents autocorrelation
functions of the backscattered signals from these
irregularities and shows how these are processed to yield
information on the drift velocities of the irregularities.
Since the radar is typically operated in an azimuth scan
mode, the Doppler data derived from the autocorrelation
functions may be used to study the two-dimensional
structure of the irregularity drift. A procedure is
presented for this analysis, and it is shown that the
results are reasonably accurate during periods in which
the irregularity drift is approximately uniform. However,
if the flow is nonuniform, as it is in the vicinity of
the cusp and in the midnight local time sector, then the
procedure leads to erroneous results. The implication are
considered that these results have on azimuth scan
measurements of plasma drift with incoherent scatter
radars, and possible ways are presented in which
measurements might be made under nonuniform flow
conditions.

ABSTRACT: (U) A procedure has been developed for treating the dynamic interaction between a separated wake and a surface undergoing an unsteady motion. The basis of the method is an unsteady (time-stepping) panel method coupled with unsteady integral boundary layer codes. Pilot codes have been developed for both two and three dimensional conditions. Results presented here are mainly from the two-dimensional code in which the various routines for controlling the dynamic wake model have been developed. Some viscous/inviscid three-dimensional results are shown. The long term objective is to treat complete aircraft configurations through high angle-of-attack maneuvers. Keywords: Unsteady; Time stepping calculations; Dynamic separated wake model; Coupled viscous inviscid calculations.

ABSTRACT: (U) An electrophysiological stimulation paradigm similar to one that produces Pavlovian conditioning was applied to synaptic inputs to pyramidal neurons of hippocampal brain slices. Persistent synaptic enhancement was induced in one of two weak synaptic inputs by pairing high-frequency electrical stimulation of the weak input with stimulation of a third, stronger input to the same region. Forward (temporally overlapping) but not backward (temporally separate) pairings caused this enhancement. Thus hippocampal synapses in vitro can undergo the conditional and selective type of associative modification that could provide the substrate for some of the mnemonic functions in which the hippocampus is thought to participate. UNCLASSIFIED REPORT

ABSTRACT: (U) Singular control problems with diffusion or Weiner process systems have been occurring with increasing frequency as models of a wide variety of applications; e.g., storage, inventory, finite fuel, consumption and investment, limits of impulsive control problems, etc. Here, the increment of the control force is not of the usual form $u(t)dt$, but is the differential of a non-decreasing and suitably adapted process. The models used (Wiener or diffusion processes) are only approximations in some sense to some 'physical' process - perhaps a 'wideband' noise driven system or a suitably scaled discrete parameter process. The optimal controls for these 'physical' processes are usually nearly impossible to obtain. Thus, it is of considerable interest to know whether the optimal (or delta-optimal) control for the diffusion model is 'nearly' optimal when applied to the physical problem, when compared to the optimal or delta optimal control for the latter problem. This is true, under broad conditions. The discounted and average cost per unit time problems are treated. The main methods are those of weak convergence theory.

ABSTRACT: (U) Visible chemiluminescence in the spectral range 200-900nm has been measured for the reactions of F atoms with allyl iodide, moniodobenzene, hexa-iodobenzene and ortho-, meta- and para-iodotoluene studied at reduced pressures (ca. 0.6 mbar). Emission was observed from electronically excited IF^+ (B), $HCF(A)$, $CH_2(A)$ and $C(d)$ and from vibrationally excited HF. Vibrational populations and rotational temperatures were obtained for the diatomic emitters. There is a strong interdependence of the relative intensity of HCF emission and the intensities of CH and CH₂, suggesting that their production may involve competing reactions of the same species. The similarity in the types of emitters and their states of formation leads to the conclusion that the same reactions, probably involving very simple species, take place in all cases. Keywords: Chemiluminescence, Iodine Monofluoride, Fluorine atoms, Organic iodides.

ABSTRACT: (U) Our studies concerning the carbonylation chemistry of early transition metal silyl complexes have led to the discovery of Cp*Cl Ta (n-COSiMe) (1, Cp* = n-C Me), a reactive n-silaacyl derivative. Recently we have found that 1 readily reacts with Lewis bases to form complexes of the type Cp*Cl Ta OC(L)SiMe, in which the Lewis donor binds to the silacylcarbon atom. Here we report the preparation and characterization of the trimethyl phosphite adduct Cp*Cl Ta 7n-OC(SiMe)P(OMe) (2) and its spontaneous Arbuzov-like dealkylation to MeCl and Cp*Cl TaN-OC(SiMe)P(OMe)O (8). The latter compound, which has been characterized by X-ray crystallography, contains an unusual n-phosphonatosilaacyl (2-) ligand. The dealkylation of trialkyl phosphites is promoted by a number of transition metal complexes. Dealkylation is usually preceded by coordination of phosphite to the transition metal. In a few cases this process appears to follow attack of the phosphite onto an electrophilic ligand bound to metal, as in the reaction reported here.

ABSTRACT: (U) This project investigated parallel/vector supercomputer architectures for solving Air Force problems, which demand the solution of partial differential equations (PDEs). We have developed an orthogonal multiprocessor (omp) architecture for efficiently implementing the SLQR and ADI methods in solving PDEs. Another parallel PDE machine architecture, called the V-tree multiprocessor, has been developed for mapping the multigrid algorithms. This V-tree is shown to be more effective than the well-known hypercube and mesh architectures. Both the omp and the V-tree architectures can demonstrate linear speedup by exploiting parallelism and vectorization. Continued efforts are needed to expand these initial studies into real hardware experiments and software simulations to verify the theoretical predictions on speedup performance.

ABSTRACT: (U) The Goose Bay high frequency radar can be
operated in a mode that allows the study of the temporal
and spatial behaviour of pulsating phenomena with a time
scale of minutes. On November 28, 1983, an event occurred
during which long period pulsations were observed in the
radar data. At this time, the field of view of the radar
included a region of the cleft immediately to the east of
the cusp. Combination of the radar data with HILAT
magnetometer data had allowed the identification of the
regions of the magnetosphere that mapped to the radar
field of view. Pulsations with 10-min and 15-min periods
were seen in a region mapping to the interior of the
magnetosphere. They had high azimuthal wave number (17-25)
and propagated eastward with a speed greater than 1 km/s.
At the same time, eastward drifting patches of
backscatter with a similar speed were seen in the region
of antisunward convection that mapped either to the solar
wind or the low-latitude boundary layer. A possible
interpretation is that antisunward disturbances
propagating along the magnetospheric boundary were
driving surface waves within the magnetosphere. Possible
types of disturbance that could cause such surface waves
are flux-transfer events or Kelvin-Helmholtz waves.

ABSTRACT: (U) The construction and performance of a photoelectron spectrometer designed for the vapor-phase study of high-temperature species is described. An inductively heated furnace is used to produce atoms and molecules in the vapor phase at furnace temperatures > 2000K. Electrical interference is eliminated using pulsed heating and gated electronics. A microchannel plate phosphor silicon-intensified-target camera detector is used for rapid data acquisition to minimize problems caused by time-dependent contamination in the ionization region. A dedicated, menu-driven, firmware-based interface, with key pad control, is utilized. The TV monitoring of the photoelectron line images and use of a video window to select data allow optimum spectral conditions to be preserved during and experiment. Results show reductions in data acquisition times of up to 90 compared to equivalent single-channel detector experiments.

ABSTRACT: (U) A polynomial time approximation algorithm
A for the problem of finding a maximal independent set
for cubic planar graphs is presented. It is shown that M
sub A > 6/7 in the case of cubic planar graphs and M sub
A = 7/8 in the case of triangle free cubic planar graphs
where M sub A is the worst-case ratio of the size of the
independent set found by A to the size of the maximum
independent set the graph input to A.

ABSTRACT: (U) An algorithm for the 3-Satisfiability
problem is presented and a probabilistic analysis is
performed. The analysis is based on an instance
distribution which is parameterized to simulate a variety
of sample characteristics. The algorithm assigns values
to variables appearing in a given instance of 3-
Satisfiability, one at a time, using the unit clause
heuristic and a maximum occurring literal selection
heuristic; at each step a variable is chosen randomly
from a subset of variables which is usually large. The
algorithm runs in polynomial time and it is shown that
the algorithm finds a solution to a random instance of 3-
Satisfiability with probability bounded from below by a
constant greater than zero for a range of parameter
values. The heuristics studied here can be used to select
variables in a Backtrack algorithm for 3-Satisfiability.
Experiments have shown that for about the same range of
parameters as above the Backtrack algorithm using the
heuristics finds a solution in polynomial average time.

ABSTRACT: (U) The problem of finding the probability density function of the output of an oscillator (a filter of higher order than the first) driven by dichotomous Markov noise (the random telegraph signal) is considered. No known theoretical methods are available for completely solving problems of this type. A somewhat general expression is derived for the output moments and an exact formulation for the probability density is presented in terms of Fokker-Planck type equations. However, partly because of irregularly shaped boundaries, the Fokker-Planck equations are complicated and remain unsolved except in the first-order case. The paper concludes with some Monte Carlo results for a second-order Butterworth filter. Keywords include: Reprints, Dichotomous Markov noise, Random telegraph signal, Probability density functions, - and Fokker-Planck equations.

ABSTRACT: (U) A time consistent global pressure relaxation procedure of the unsteady, compressible, reduced Navier Stokes equations is presented. The shock capturing capability of the procedure is investigated with different forms of pressure gradient splitting. An efficient conservative method for capturing shocks is detailed. The transient behavior of laminar, high Reynolds number, low subsonic flow past a sine-wave airfoil geometry is analyzed using the new reduced Navier Stokes based algorithm. These solutions are compared with steady and unsteady results previously obtained with a modified interacting boundary-layer procedure. The strong influence of grid refinement and the type of differencing of the streamwise convection term on the existence or stability of separated laminar solutions is reaffirmed. More stable turbulent flow results are also presented. Finally, an unsteady solution for the flow past a finite flat plate at incidence is described in order to demonstrate the time accuracy of the algorithm.

DESCRIPTORS: (U) *COMPRESSIBLE FLOW, *NAVIER STOKES EQUATIONS, ACCURACY, AIRFOILS, BOUNDARY LAYER, CONVECTION, FLAT PLATE MODELS, GEOMETRIC FORMS, GRIDS, HIGH RATE, INTERACTIONS, LAMINAR FLOW, PRESSURE GRADIENTS, REDUCTION, RESPONSE, REYNOLDS NUMBER, SINE WAVES, SOLUTIONS(GENERAL), STABILITY, SUBSONIC FLOW, TRANSIENTS, TURBULENT FLOW, FLOW SEPARATION, TIME STUDIES, REPRINTS.

ABSTRACT: (U) A projection theorem is obtained for the class of far field patterns of the acoustic transmission problem corresponding to time-harmonic incident plane waves propagating in arbitrary directions. This projection theorem depends on the eigenvalues of a new class of boundary value problems associated with the transmission problem. This projection theorem and the theory of Herglotz wave functions, is used to derive two distinct optimization schemes for solving the inverse transmission problem. Numerical examples are then given showing the practicality of the second of these two methods for solving the inverse transmission problem.

DESCRIPTORS: (U) *INVERSE SCATTERING, *SOUND TRANSMISSION, *ACOUSTIC SCATTERING, ACOUSTIC WAVES, BOUNDARY VALUE PROBLEMS, EIGENVALUES, FAR FIELD, HARMONICS, INVERSION, OPTIMIZATION, PATTERNS, PENETRATION, PLANE WAVES, TIME, TRANSMITTANCE, WAVE FUNCTIONS, REPRINTS.

IDENTIFIERS: (U) Herglotz wave functions, Inverse transmission problem, Projection theorems.

and Applications, v53 n1 p85-104 Apr 87.

ABSTRACT: (U) One-step algorithms are presented for two
classes of structured stochastic games, namely, those
with additive rewards and transitions and those which
have switching controllers. Solutions to such classes of
games under the average reward criterion can be derived
from optimal solutions to appropriate bilinear programs.
The validity of using bilinear programming as a solution
method follows from two preliminary theorems, the first
of which is a complete classification of undiscounted
stochastic games with optimal stationary strategies. The
second of these preliminary theorems relaxes the
conditions of the classification theorem for certain
classes of stochastic games and provides the basis for
the bilinear programming results. Analogous results hold
for the discounted stochastic games with the above
special structures. (Reprints)

ABSTRACT: (U) It is shown that Bush's bound for maximum number of constraints in an orthogonal array of index unity is uniformly better than Rao's bound. In addition it is shown, using an argument similar to that needed in the proof of the above result, that Noda's characterization of parameters in orthogonal arrays of strength 4 achieving equality in Rao's bound, leads easily to a similar characterization in arrays of strength 5. These results are useful designing experiments for quality control.

ABSTRACT: (U) There has been considerable disagreement about how best to estimate the parameters in Michaelis-Menten models. This document points out that many fitting methods are based on different stochastic models, being weighted least squares estimates after appropriate transformation. The authors propose a flexible model which can be used to help determine the proper transformation and choice of weights. The method is illustrated by examples. Keywords: Nonlinear regression; Lineavever Burke transformation.

ABSTRACT: (U) This result is proved. If sub n is a separable metric space for $n \rightarrow \infty$, then sub n approaches limit of S sub n infinity is measurable for $n \rightarrow \infty$, X sub n is an S sub n valued random variable for $n \rightarrow \infty$ and phi sub n (X sub n) approaches limit of sub x sub n infinity in S sub n infinity, then there exists S sub n valued random variables X sub n such that X sub n = d sub x sub n for $n \rightarrow \infty$ and phi sub n (X sub n) approaches limit of X sub n infinity wpl. Conditions on S sub n and phi sub n are presented that allow a construction in the context of Polish spaces.

ABSTRACT: (U) Calculations have been made of O₂ absorption and fluorescence in the Schumann-Range B from X band system for excitation by a broadband argon fluoride excimer laser at 193nm. Results are presented for line strengths, spectral absorption coefficients, relative fluorescence spectra, total fluorescence and integrated absorption coefficients. The calculations have been performed for 300, 500, 1000, 1500 and 2000 K, a range of temperatures typically found in combustion flows. The absorption coefficients and fluorescence yields found are very large enough to encourage use of argon fluoride lasers for O₂ measurements in a variety of flows. ABSTRACT: (U) This document examines the paths of the stable fields that are the analogs of index-beta Gaussian fields. The author finds Holder conditions on their paths and finds the Hausdorff dimension of the image, graph, and level sets when we have local nondeterminism, generalizing the Gaussian results. Keywords: Inversion; random variables.

ABSTRACT: (U) The paper presents some recently obtained results on the nonlinear filtering problem for infinite dimensional processes. The optimal filter is obtained as the unique solution of certain measure valued equations. Robustness properties - both pathwise and statistical - are given and a preliminary result shows consistency with the stochastic calculus theory. Applications to random fields and models of voltage potential in neurophysiology are briefly discussed. Keywords: Markov processes; white noise.

ABSTRACT: (U) Skorohod has shown that the convergence of sums of i.i.d. random variables to an alpha-stable Levy process, with $0 < \alpha < 2$, holds in the weak J sub 1 sense. It is shown that for sums of moving averages with at least 2 non-zero coefficients, weak J sub 1 convergence cannot hold, however, if the moving average coefficients are positive, weak J sub 1 convergence usually does hold. Keywords: bisection method; sequences (mathematics).

ABSTRACT: (U) A generalized shot noise in Banach spaces is defined as the a.s. limit of certain centered sums of dependent random vectors; and, a necessary and sufficient condition for its existence is given. UNCLASSIFIED REPORT

ABSTRACT: (U) It is well known that point process methods can be applied effectively to study certain types of problems in statistical extreme value theory. Consider a strictly stationary sequence of random variables (x_i) indexed by the set of integers $I=Z$. One can define a number of interesting point processes in one dimension by recording the positions where extreme values occur. For example, an extremal process typically is one that records the indices (properly normalized) at which record values of x_i sub 1, x_i or sub 2 occur, and an exceedance point process considered by Leadbetter consists of the set of points $j.n: x_i$ sub $j > w$ sub n , where sub n is a suitable sequence of constants. For this type of processes, Poisson or compound Poisson convergence results can often be derived under suitable mixing conditions. Keywords: Weak convergence.

ABSTRACT: (U) Translates of symmetric stable and other p sub th order processes are considered. An upper bound for the set of admissible translates of a general p sub th order process is presented, which is a partial analog of the reproducing kernel Hilbert space of a second order process. For invertible stable processes a dichotomy is established, i.e. each translate is either admissible or singular, and the admissible translates are characterized. As a consequence, most continuous time moving averages and all harmonizable processes with nonatomic spectral measure have no admissible translate; and the admissible translates of a general harmonizable process are characterized. The translates of a mixed autoregressive moving averages stable sequence are shown to coincide with those of the Gaussian case.

ABSTRACT: (U) This is a reprint version of an article written at the request of the International Statistical Review. The article is organized in three main sections. The first of these is a brief overview of Harald Cramer's life and career. The second (and main) section is an account of his work in Probability and Statistics, with historical perspective where possible. The third, final section contains personal comments and recollections from the author's own contacts with Harald Cramer. These are intended to complement the description of the career and scientific contributions of Cramer, with some glimpses of his personal qualities. Keywords: Stationary processes; Insurance risk; Markov processes.

ABSTRACT: (U) A stochastic control problem is obtained as a small noise approximation to a deterministic optimal control problem. Two classes of admissible controls are considered and the optimal control policies are explicitly determined for a each admissible class. The larger admissible class contains controls referred to as singular stochastic controls. For this class, the cumulative effect of control has bounded variation trajectories. The smaller admissible class contains the standard stochastic controls whose cumulative effect has absolutely continuous trajectories. These controls are referred to as absolutely continuous controls. The optimal singular control provides a cost strictly smaller than the minimum cost achievable when only absolutely continuous stochastic controls are admissible. In particular, this shows that is not always possible to approach the optimal cost for singular control is only the standard stochastic control policies are admissible. Keywords: Hamilton-Jacobi-Bellman equation.

ABSTRACT: (U) Free boundary problems are defined and illustrated by several problems in mechanics. First the problem of finding the free surface of a liquid in hydrostatic equilibrium is considered. Then the effect of surface tension is taken into account. Finally the contact of an inflated membrane, such as a balloon or tire, with a solid surface is formulated. This problem is solved by the method of matched asymptotic expansions when the contact area is small. Keywords: reprints; hydrostatics; surface tension; axial symmetry.

ABSTRACT: (U) The objective of this research investigation was to determine, experimentally and analytically, the physical mechanisms that control the behavior of continuous, laser sustained plasmas. The principle questions involve the effects of a forced convection environment and optical geometry on the stability, fractional power absorption, plasma structure, and fluid mixing. A continuous, 1.5 kW, axial flow, carbon dioxide laser was used to create the LSP in a cylindrical quartz flow channel. The convection flowfield surrounding the plasma was controlled by the volume flow through the test chamber, and the optical geometry was determined by the unstable oscillator output mode of the laser and the focal length of the lens. Digital images of the plasma in a selected narrow wavelength interval were obtained using a CID digital camera and a VICOM digital image processing computer that were calibrated for absolute radiance. These images were then Abel inverted to give a spatial plasma emission coefficient which determined the spatial distribution of the plasma temperature. These measured temperature fields were then used to calculate the laser power absorption in the plasma and the power lost from the plasma through optically thin emission. More than one hundred sets of data were obtained for argon plasmas at nominal pressures from 1.5 to 3 atmospheres and incident flow velocities from 0.4 to 4.0 m/s.

ABSTRACT: (U) An analysis was developed describing the spatial parallel flow development of disturbances that are introduced into an incompressible laminar boundary layer by a vibrating ribbon at the wall. The dominant mode is corresponding to the eigenmode of the flow at the ribbon frequency, as found by Gaster, but the solution technique does not require the questionable assumptions previously invoked. Analysis of the compressibility introduces additional complexities, including the stagnation enthalpies of the two streams, and admits influences of higher acoustical modes. Keywords: Compressible free shear layers.

ABSTRACT: (U) A mathematical model is presented for determining the composition of extended solid solution formed due to rapid cooling in laser cladding. This model considers a diffusion mechanism for mass transport in a one-dimensional semi-infinite molten pool of the cladding material from which heat is removed by conduction through a one dimensional semi-infinite solid substrate. The rate of solidification has been obtained by modeling the cooling process as a composite medium heat transfer problem. The discontinuity of the concentration field has been simulated using a nonequilibrium partition coefficient, and then a nonsimilar exact solution for the mass transport equation has been obtained using a set of similarity variables which has been derived using Lie group theory.

ABSTRACT: (U) Problems arising in the area of nonlinear vibrations were studied. Essentially equations such as that for a periodically forced, damped pendulum are capable of exhibiting behavior which was unsuspected even 10 years ago and the principal investigator was in the forefront to the effort to explain these mysteries. It was he who coined the term 'chaos' and the students and publications here identified are confined to that topic. Dr. Yorke reports on work to determine the factual dimension of attracting sets for differential equations together with some vigorous results on the dependence of such sets on equation parameters.

ABSTRACT: (U) The objective of this research is to clarify the mechanisms responsible for the suppression of soot in flames by fuel additives. Measurements are limited to well-defined hydrocarbon/air prevaporized liquid- and gaseous-fueled flames. Emphasis is given to ferrocene in a diffusion flame fueled by prevaporized iso-octane. Nonperturbing laser/optical diagnostic techniques are used to relate changes in soot particulate size, number density, and volume fraction to additive concentration. Ferrocene is observed to suppress a visible soot plume completely and, in general, to intervene at a late combustion stage. Suppression is due to both size and number density reduction, which suggests that ferrocene enhances the oxidative burn-out of soot. In contrast, at an early combustion stage nearer the burner lip, a slight enhancement of soot observed with ferrocene seeding. Keywords: Additive, Ferrocene, Flame, Soot.

ABSTRACT: (U) A variety of scientific investigations of outstanding interest are now possible using an atomic physics facility (APF) based on the combination of an undulator or wiggler as a high-brilliance synchrotron light source, a synchrotron storage ring for heavy ions, and a tandem accelerator or other source of highly ionized atoms for filling the storage ring. The APF opens dazzling new vistas for qualitatively new experiments in atomic physics and related fields since it gives improved reaction rates, provides refined energy resolution, and produces copious quantities of multiply ionized atoms in well-defined states. The APF represents a way of combining new techniques into a powerful, well-coordinated facility to deal comprehensively with the new atomic physics. The science that can be done with the APF is discussed mainly from the general view of what can be done with synchrotron radiation. The storage ring can also be used completely independently with lasers or to study ion-electric, ion-atom, or ion-ion interactions. Together, electron and heavy-ion storage rings provide an extraordinarily large number of ways of preparing and probing atoms and molecules. By employing complementary experimental methods at a single facility, the APF makes it possible to choose the very best experimental

SUPPLEMENTARY NOTE: Pub. in Jnl. of Physical Chemistry, v91 n9 p2230-2232 1987.

ABSTRACT: (U) The adsorption of benzene on the Ni (100) and the Ni (111) crystal faces was compared in order to investigate the effect of crystallographic orientation on the interaction of benzene with nickel. Temperature programmed reaction (TPR) was used to characterize adsorption bond strengths and determine product distributions. Benzene was found to adsorb 44 kJ/mol less strongly on the Ni(111) plane than on the Ni(100) surface. Di hydrogen evolution formed after decomposition of benzene was similar for both surfaces. Benzene chemisorption was modeled by using extended Huckel theory (EHT), a semiempirical molecular orbital method. The calculations predict bonding of benzene over a three-fold hollow site on Ni(111). Multicenter bonding of the benzene carbon atoms with the nickel atoms is indicated by the calculations. The binding strength of benzene is controlled by the degree of overlap of the carbon orbitals with the nickel atom orbitals. Benzene binds more strongly to the Ni(100) surface because of the carbon pi orbitals can overlap with four nickel atoms on the fourfold hollow site, whereas on Ni(111) the carbon atoms are closely associated with only three nickel atoms on the threefold hollow site. Keywords: Nickel, Benzene, Extended Huckel theory, Molecular bonding.

ABSTRACT: (U) Coherent thin films of poly(bis(p-toluene sulfonate) diacetylene) were successfully formed by modified Langmuir-Blodgett techniques using two methods: (i) photopolymerization of the monomer film at the gas/liquid interface and then transfer to a solid substrate, and (ii) transfer of the monomer film to the solid substrate and subsequent photopolymerization on the substrate itself. The films thus obtained were characterized by traditional force-area isotherms while on pure water subphases. Segments were transferred at either 1 or 10 dyn/cm surface pressure, in different stages of photopolymerization, to glass or germanium substrates. The films on the substrate were characterized by the methods of multiple attenuated-internal-reflection infrared spectroscopy, ellipsometry, contact-potential measurement, and laser Raman spectroscopy. Our results show that the films are multimolecular and about 100 Å thick. Of special interest were the observation of significant anisotropy of oriented dipoles and the ability to obtain excellent spectral data for these very thin oriented films. Raman spectroscopic features are similar to those observed for the bulk polymer, even in the low-frequency region. Polarized Raman spectroscopy

UNCLASSIFIED REPORT

ABSTRACT: (U) In this paper, the authors derived asymptotic joint distributions of the eigenvalues of some random matrices which arise under components of covariance model. Keywords: Eigenstructure analysis; Multivariate analysis; Analysis of variance.

ABSTRACT: (U) In a number of situations, the experimenter is confronted with the statistical analysis of the data which is binary in nature. For example, one may be interested in diagnosis of the disease on the basis of symptoms. The reliability of complicated systems can be studied by examining as to whether its components are functioning or not. In image processing, a picture is classified on the basis of two grey levels like white and black using some threshold value. We may assign a score of 1 or 0 according as the grey level is white or black respectively. So, it is important to study the problems of estimation of multivariate binary density. Cencov expressed continuous multivariate density as a series of orthonormal functions. Bahadur expressed the multivariate binary density as a series. Ott and Kromal expressed the density as a series involving Walsh functions. Liang and Krishnaiah also expressed the density in terms of Walsh functions but the coefficients in their series are different from those used by Ott and Kromal. This paper is a continuation of the work done by Liang and Krishnaiah.

UNCLASSIFIED REPORT

ABSTRACT: (U) The concepts of metrics and distances are fundamental in problems of statistical inference and in practical applications to study affinities among a given set of populations. A statistical model is specified by a family of probability distributions, described by a set of continuous parameters known as the parameter space. This model possesses some geometrical properties which are induced by the local information matrix of the given family of distributions gives rise to a Riemannian metric over the parameter space, whose geodesic distance, known as the Rao distance, plays a major role in the multivariate statistical techniques. For the family of multivariate normal distributions with fixed shape but varying locations, this distance reduces the well-known Mahalanobis distance. This document refers to Burbea and Rao for more details on these concepts and their derivations. An interesting statistical model is provided by the family of elliptic distributions whose density functions have elliptical contours and which include the multivariate normal distributions as a subfamily. This paper studies the information metric associated with an elliptic family whose shape varies linearly.

ABSTRACT: (U) Measurements of structure angle in a
supersonic turbulent boundary layer with zero and adverse
pressure gradients are presented. Conditionally sampled
measurements of u, v , and w are presented along with
quadrant analysis of the turbulent fluctuations. The
latter suggests ambiguities associated with the
interpretation of VITA measurements. Preliminary results
of experiments on artificially generated hairpin vortices
are also discussed. Measurements indicate a high degree
of similarity between the signatures of these hairpin
structures and ensemble averaged events in the turbulent
boundary layer. Keywords: Turbulence, Boundary layer,
Supersonic Flow.

ABSTRACT: (U) In stochastic scheduling and optimal
maintenance problems that have been considered in the
literature, the optimization criterion used has often
been equivalent to minimizing the expected first passage
times to a set of states. A typical method used in
establishing the optimality of a certain policy is the
method of successive approximations on the appropriate
dynamic programming functional equations. As an
intermediate result, this technique often involves the
optimality of the pertinent policy for all finite horizon
versions of the problem. This paper characterizes
stochastically optimal policies as policies that process
a similar property, i.e. these are optimal in expectation
for all members of a sequence of appropriately defined
finite horizon problems. The authors use this
characterization to establish the stochastic optimality
of relevant policies for the optimal repair allocation
for a series system problem and for a scheduling problem.

ABSTRACT: (U) Based on right censored data from a lifetime distribution F sub 0, a modification of the kernel quantile estimator is proposed. The advantage of this estimator is that the data play a role in the degree of smoothing of the estimator while retaining the desirable features of the kernel estimator. Convergence in probability and almost sure convergence of the estimator are discussed. Some examples are given which illustrate the differences between this modified estimator and the fixed-bandwidth kernel quantile estimator for randomly right-censored data. Keywords: Random censoring; Product-limit quantile function; Kernel type quantile estimator; Nonparametric quantile estimation.

ABSTRACT: (U) The principle object of the research was to provide a better understanding of the behavior of the soil-structure interaction phenomena associated with buried conduits subjected to airblast loads. A parametric study was performed to experimentally determine the effects of airblast loads on 4-in diameter micro-concrete pipes, embedded horizontally in a dry sand. The parameters varied in the study included the gravity level, the applied airblast pressure level, the relative density of the dry sand, burial depth of the structure, and the relative stiffness between the structure and the soil. A geotechnical centrifuge was used to create the proper in-situ stress conditions in the sample during each test. Dynamic stress gages were utilized to measure the applied airblast on the sample surface, the normal stresses acting at the soil-pipe interface, and in the free-field conditions. Proximitors positioned inside of the structures were used to measure the resulting deflections. The results of the experimental study verified the importance of testing models at increased gravity levels, and determined the feasibility of the dynamic stress gages for measurement of contact and free-field stresses.

SUPPLEMENTARY NOTE: See also Volume 3. AD-A186 361.

ABSTRACT: (U) Soil-Structure Interaction under blast loading was investigated both experimentally in 10 g-ton centrifuge and analytically by finite element simulation. In the centrifuge experiments, circular pipes made of micro-concrete were buried in a dry sand and tested in the centrifuge to simulate the effects of gravity-induced overburden stresses which played a major role in controlling the soil stiffness and, subsequently, the response of the pipe. The blast loading was simulated by a pressure pulse generated by rupturing a burst disc in an impact generator. Surface stress gages and contact stress gages both made of polyvinylidene fluoride were built and calibrated to measure air blast magnitudes and contact pressures. The centrifuge experiments provided insight into the dynamic response of buried pipes and a data base for the verification of numerical results. These results were obtained by linear and non-linear finite element analyses of the experiments duplicating the surface overpressure loading. The suitability of constitutive relations for both soil and micro-concrete were verified by comparing test results and analysis. The effects of soil arching around the buried pipe was also

ABSTRACT: (U) The authors present a method for
constructing an orthonormal basis for a symmetry class of
tensors from an orthonormal basis of the underlying
vector space. The basis so obtained is not composed of
decomposable symmetrized tensors. Indeed, we show that,
for symmetry classes of tensors whose associated
character has degree higher than one, it is impossible to
construct an orthogonal basis of decomposable symmetrized
tensors from any basis of the underlying vector space. We
end with an open problem on the possibility of a symmetry
class having an orthonormal basis of decomposable
symmetrized tensors. (Reprints).

ABSTRACT: (U) Both laboratory and in-flight studies were carried out in order to evaluate the utility and feasibility of EEG monitoring as a means of identifying central nervous system correlates of performance and G-force effects during military flight operations. Four studies were conducted, two with controlled laboratory simulation, and two in actual flight during military training missions. Data analysis focused on EEG power-spectral density characteristics and their temporal modulation, specifically in sensorimotor and visual cortical areas. Several consistent findings emerged. During competent performance, a highly unique discrepancy appeared between left and right hemispheres in central 8-15 Hz activity. This pattern disappeared as performance degraded. The temporal modulation of this activity also reflected these changes. During high G-force situations, power at frequencies below 8 Hz was progressively and non-specifically enhanced. Continued competent performance, however, was still reflected by the pattern described above. These findings are discussed in terms of their neurophysiological implications.

ABSTRACT: (U) Thermal reaction of a hexane solution of octafluorocyclooctatetraene (OFOT) with either Co(Cp*)(CO) 2 or Rh(Cp*)(C2H4)(Cp* = eta-C5Me5) in the dark afforded good yields of the complexes M(eta-C5Me5)-(1,2,5,6-eta-C8F8) (11a, M = Co; 11b, M = Rh). Photolysis of solutions of 11a, b at different temperatures afforded a photostationary 2.3:1.0 mixture of the starting complexes and the isomeric compounds M(eta-CMe5)(1,2,3,6-eta-C8F8) (12a, M = CO; 12b, M = Rh). The ratio of isomers is independent of M and the photolysis temperature. Heating each mixture in the dark results in quantitative conversion to pure isomer 11. One-electron reduction of 11a results in an ECE mechanism. The first electron-transfer step produces the radical anion 11a-, in which the mode of ligation of OFOT to cobalt is maintained and in which ESR studies show the half-filled orbital to be located primarily on the metal. Subsequent reaction of this radical anion occurs to give an electrochemically active product that was too unstable to characterize. Keywords: Fluorine compounds, Cyclic compounds.

ABSTRACT: (U) A percept of global coherent motion can result from the combination of many different localized motion vectors. We report evidence of hysteresis in the perception of this global motion, obtained with random-dot cinematograms. The hysteresis characteristics are relatively robust with respect to changes in dot density, display area, and location. Changing the directional content of the stimulus, however, did alter the hysteresis profile in a manner consistent with a model incorporating cooperative interactions among direction-selective motion mechanisms. Our results lend further support to a cooperative interpretation of motion perception in random-dot cinematograms. Keywords: Visual perception. (Reprints)

ABSTRACT: (U) The 42nd Symposium on Molecular Spectroscopy was convened at Ohio State University during the period 15-19 June 1987. Over 300 scientists attended, representing research organizations from the U.S. and fourteen foreign countries. Topical areas included electronic characteristics of molecules, energy transfer, infrared and microwave spectra, liquid and solid state phenomena, laser spectra, Raman spectra, molecular beams, vibrational analysis, and experimental techniques. As planned, special emphasis was placed on the spectroscopy of van der Waals molecules, and there was a special session on probing and modeling the earth's atmosphere.

EVJ38K

ABSTRACT: (U) The finite element method has three versions: the h-version, the p-version and the h-p version. In the h-version, increased accuracy is achieved by decreasing the mesh size h while keeping p , the degree of elements used fixed (usually $p = 1, 2, 3$). In the p-version, a fixed mesh is used while the degree p of elements are either uniformly or selectively increased to achieve accuracy. The h-p version is a combination of both. The standard h-version has been thoroughly investigated and many commercial and research programs are available. The p- and h-p versions are recent developments. There is only one commercial code, the system PROBE, and the first papers discussing theoretical aspects appeared only in 1981. The approximations of solutions of elliptic problems of order 21 over two-dimensional polygonal domains by the p-version of the finite element is investigated. Optimal rates of convergence are established for the case when elements possessing C continuity are used.

UNCLASSIFIED REPORT

ABSTRACT: (U) In estimating and comparing the rates of change of a continuous variable between two groups, the unweighted averages of individual simple least squares estimates from each group are often used. Under a linear random effects model, when all individuals have completed observations at identical time points these statistics are maximum likelihood estimates for the expected rates of change. However, with censored of missing data, these estimates are no longer efficient when compared to generalized least squares estimates. When, in addition, the right censoring process is dependent upon the individual rates of change (i.e., informative right censoring), the generalized least squares estimates will be biased. Likelihood ratio test for informativeness of the censoring process and maximum likelihood estimates for the expected rates of change and the parameters of the right censoring process are developed under a linear random effect models with a probit model for the right censoring process. In realistic situations, we illustrate that the bias in estimating group rate of change and the reduction of power in comparing group difference could be substantial when strong dependency of the right censoring process on individual rates of change is ignored. ABSTRACT: (U) A number of important recent advances in econometric theory are related to the methods of truncated regression model - the regression model in which the range of the dependent variable is restricted to some interval of $(-\infty, \infty)$, usually the non-negative half-line, such as the income of an individual. Powell used the L sub 1-norm criterion with some modifications in estimating the regression coefficients in truncated linear models. He proved the consistency and asymptotic normality of his estimates under a set of conditions. On the other hand, Nawata's paper uses the ordinary L sub 2-norm (least square) criterion, along with a grouping and adjustment of the observed data. In his view, his method has the merit of easy computation compared with the method of Powell. This paper borrows the basic idea of Nawata in grouping and adjusting the observed data. But the authors make simplifications in the procedure of grouping, which enables us to make substantial extensions of the results of Nawata's paper under weakened conditions. Keywords: Linear median regression; Truncated regression; Parameters; Linearity.

ABSTRACT: (U) The set of all bivariate distributions with support contained in $((1,j); 1 = 1,2 \text{ and } j = 1,2, \dots, n)$ which are positive quadrant dependent is a convex set. In the paper, an algebraic method is presented for the enumeration of all extreme points of this convex set. Certain measures of dependence, including Kendall's tau, are shown to be affine functions on this convex set. This property of being affine helps us to evaluate the asymptotic power of tests based on these measures of dependence for testing the hypothesis of independence against strict positive quadrant dependence. Keywords: Multivariate analysis; Asymptotic; Random variables; Probability distribution functions.

ABSTRACT: (U) Several aspects of adaptive methods for partial differential equations implemented on vector and parallel computers were investigated on this effort. A new technique for mapping mesh points to processors in a static way has been developed, this takes advantage of the structure of the family of solutions without singling out any one solution. Three publications and two technical reports resulted from this effort, as well as two conference proceedings papers and four presentations. Papers included such titles as A comparison of domain decomposition techniques for elliptic partial differential equations and their parallel implementation, Local uniform mesh refinement on loosely-compiled parallel processors, and Dynamic grid manipulation for partial differential equations on hypercube parallel processors. UNCLASSIFIED REPORT

ABSTRACT: (U) Under the current grant parallel hardware and systems software implemented on ZMOB in the previous year underwent extensive testing. A parallel problem solving system, PRISM (Parallel Inference System) implemented on the VAX/11-780 in the previous year was implemented on the PYRAMID and SUN machines. The initial version of PRISM uses a simulation of the ZMOB hardware, and has been fully tested and debugged. Experimental testing of PRISM on the simulated system was undertaken in the current year. In addition, several enhancements were made to PRISM to permit experimental analyses to be made, and to incorporate additional features to take full advantage of parallelism in a problem solving environment. The tracing and statistical gathering packages were extended. An AND-parallelism capability was added to achieve a second version of the PRISM system, and other features were added to the system to more fully exploit parallelism. A constraint solving machine was integrated with PRISM. In addition to the above, a general method to permit informative answers to be presented to a user has been developed. Theoretical results were obtained for circumscription and a method for computing in protected circumscription, using Horn clauses was developed. In the area of systems hardware and software, the ZMOB processor is now fully functional and in everyday use with 128 processors.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper studies the connectedness of 3 dimensional designs by reducing the dimension of designs from three to two. A new graphical method of determining the connectedness of designs is presented. The method is easier and simpler than the earlier known methods of Birkes, Dodge and Seely (1978) and Srivastava and Anderson (1970). A generalization of this method for 4 or higher dimensional designs is also discussed.

DESCRIPTORS: (U) *GRAPHS, *FACTORIAL DESIGN, THREE DIMENSIONAL, SIZES(DIMENSIONS), CONTRAST, RANDOM VARIABLES, REDUCTION.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper gives a simple construction of the general stationary regenerative set, based on the stationary version of the associated subordinator (increasing Levy process). It is shown that, in a certain sense, the closed range of such a Levy process is a stationary regenerative subset of R. The distribution of this regenerative set is delta-finite in general; it is finite if the increments of the Levy process have finite expectation.

UNCLASSIFIED REPORT

ABSTRACT: (U) This work studied discharge processes in Knudsen mode (collisionless), thermionic energy converters. Mechanisms for reducing the effects of electron space charge in such devices are essential for thermionic converters to produce useful current and power densities. The mechanisms studied are: reduction of space-charge through a very close interelectrode gap (less than 10 microns); transport and retention of positive cesium ions generated by surface ionization; transport of positive cesium ions generated in an arc external to the electrodes; and the mechanism for enhanced current output due to a structured emitter in a mixed barium-cesium vapor. The experimental work used SAVTEC (Self-Adjusting, Versatile Thermionic Energy Converter) diode structures which were tested in a chamber containing 0.1 - 1.0 torr of cesium vapor. Comparison of measured volt-ampere curves with theory gave excellent agreement and indicated an interelectrode gap of 8.5 microns at an emitter temperature of 1250 K. A theoretical model of the collisionless thermionic diode was developed which included surface ionization, auxiliary ions from an external source, and trapping of charged particles in potential wells due to infrequent collisions. Studies showed that trapping of positive ions leads to a large,

beneficial increase in current density. Using a diffusion analysis to couple this model to models of collision-dominated discharges gave predictions of the performance of SAVTEC devices in the presence of an auxiliary discharge, and led to design criteria for electrode size in order for auxiliary ionization to be effective.

ABSTRACT: (U) Efforts during this period were largely devoted to the study of three specific problems: (1) The estimation of the lifetime distribution of a system subject to imperfect repair; (2) the estimation of a life distribution known to belong to the class of distribution for which new is better than used in expectation; and (3) Multivariate modeling of the joint distribution of component lifetimes for systems under repair. Results are discussed below. Results have been obtained on two additional problems: Parametric modeling and inference for random records and general modeling of the multivariate lack of memory property.

UNCLASSIFIED REPORT

ABSTRACT: (U) In stochastic scheduling and optimal maintenance problems that have been considered in the literature, the optimization criterion used has often been equivalent to minimizing the expected first passage times to a set of states. A typical method used in establishing the optimality of a certain policy is the method of successive approximations on the appropriate dynamic programming functional equations. As an intermediate result, this technique often involves the optimality of the pertinent policy for all finite horizon versions of the problem. This paper characterizes stochastically optimal policies as policies that process a similar property, i.e. they are optimal in expectation for all members of a sequence of appropriately defined finite horizon problems. The authors use this characterization to establish the stochastic optimality of relevant policies for the optimal repair allocation for a series system problem and for a scheduling problem. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Recursive M-estimators of location and scale may be obtained via stochastic approximation algorithms. We consider the case when the observations can be described by a strictly stationary process satisfying certain strong mixing conditions and results on strong convergence are given. The asymptotic distributions of the estimators for sequences of independent observations are also discussed.

ABSTRACT: (U) The goal of this program is to understand turbulence chemistry interactions in combustion up to and including localized extinction. Experimentally, pilot stabilized non premixed turbulent jet flames of selected mixtures are being studied under conditions conducive to strain-induced local extinction. Laser based techniques such as Raman scattering and Rayleigh scattering are employed. Analytically, models based on the asymptotically thin flamelet concept and on distributed reaction zone concepts are being assessed. A significant finding is that the popular contemporary view of a turbulent flame as an ensemble of asymptotically thin flamelets seems incorrect. Alternative mechanisms based on thick flamelets are proposed. The results include: (1) A complete re evaluation of Raman data showing significant corrections due to high temperature effects. Keywords: Turbulence chemistry interactions, Extinction, Blowoff, turbulent diffusion flames, Superequilibrium, Laser diagnostics.

ABSTRACT: (U) In the past year we have implemented prototypes of components of the Saguaro distributed operating system and refined the design of the entire system based on the experience. The philosophy behind Saguaro is to support the illusion of a single virtual machine while taking advantage of the concurrency and robustness that are possible in a network architecture. Within the system, these advantages are realized by the use of pools of server processes and decentralized allocation protocols. Potential concurrency and robustness are also made available to the user through low-cost mechanisms to control placement of executing commands and files, and to support semi-transparent file replication and access. Another unique aspect of Saguaro is its extensive use of type system to describe user data such as files and to specify the types of arguments to commands and procedures. This enables the system to assist in type checking and leads to a user interface in which command-specific templates are available to facilitate command invocation. A mechanism, channels, is also provided to enable users to construct applications containing general graphs of communication processes. Keywords: SR distributed programming language.

ABSTRACT: (U) This report lists the equipment purchased with the funds provided under Grant Number AFOSR-83-0315 and describes the use which has been made of the equipment in support of Department of Defense sponsored and other research projects. The funds provided by the grant were combined with matching funds from the University of Texas to create an environment for experimental research in parallel computer design and development environment and a software development environment. The hardware design and development environment includes capabilities for the design and validation of chips and printed circuit boards. The software development environment includes a software-rich superminicomputer and a set of low-power graphics workstations. The hardware which was purchased includes a Digital Equipment Corporation VAX 11/750 computer system, Tektronix high speed digital logic analyzer, a Valid Logic Corporation workstation with the Scald design package and several Apple Macintoshes to be used as terminals and low-power workstations. A portion of the funds in the AFOSR grant was used to purchase printed circuit boards to complete the four-processor nine-memory unit configuration of the Texas Reconfigurable Array Computer (TRAC).

UNCLASSIFIED REPORT

ABSTRACT: (U) There are four projects underway that either have used the equipment purchased using the funds from this grant or will use the equipment in the near future. Titles and abstracts of the representative papers describing these projects follow. It is the first project the Saguaro Distributed Operating System that formed the basis for the URIP grant proposal.

ABSTRACT: (U) In this paper, we have shown that we can characterize methods for the solution of incompressible flow problems as belonging to either parabolic or elliptic type with regard to the determination of pressure field. The elliptic schemes typically have smaller errors in the divergence field, with the errors decaying exponentially away from the boundaries of the computational domain. On the other hand, the parabolic schemes have smooth solutions, without numerical boundary layers, but care should be exercised with respect to the boundary conditions in order that initial divergence errors be eliminated. This analysis explains why elliptic schemes, like that introduced by Harlow Welch (1985) have been found to be more accurate than parabolic schemes.

ABSTRACT: (U) This paper studies how sampling variation in component reliability estimates affects the computation of system reliability that uses these estimates as input. Results show that relative bias in system reliability grows quadratically with the number of components for which each component reliability estimate is used whereas the corresponding coefficient of variation grows linearly with this number of components. If these components are in parallel they lead to an understatement of system reliability. In series, they lead to an overstatement. The paper describes resampling schemes that eliminate bias without increasing the dominant variance term. (Keywords: operations research; systems analysis; statistical accuracy).

UNCLASSIFIED REPORT

ABSTRACT: (U) A fifteen-month multi-task research project was pursued by the present investigators to study complex viscous flows under AFOSR sponsorship between July 1985 and September 1988. The major objective of this study was to require improved understanding of viscous flows and to develop basic computational methods for efficient determination of 2-D/3-D subsonic and incompressible flows. Two major analyses were pursued. These include the Interacting Parabolized Navier-Stokes (IPNS) analysis for steady flows and the full Navier-Stokes (NS) analysis for direct simulation of unsteady flows. The IPNS analysis developed employs no ad hoc artificial dissipation and, in spite of being a density-based formulation, performs well even for very low Mach numbers. The applications considered include 2-D cascades and channels of simple geometry. Keywords: Viscous Flows, Flow separation, Unsteady flows, Interacting equations, Multi Block structured grids, Three dimensional flows.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in International Conference on Numerical Methods in Fluid Dynamics (8th) New York, NY 1985.

ABSTRACT: (U) The calculation of viscous supersonic flow over circular cones at high angles of yaw has been partially carried out. The flow field was calculated as the interaction between the outer inviscid flow and an inner conical boundary layer flow. The latter was treated by the orthonormal version of the Method of Integral Relations (M.I.R.) and continued up to the cross flow separation line. This work deals with the boundary layer downstream of this separation line where the circumferential velocity component, w , is reversed. The orthonormal version of M.I.R. needs to be modified in this region to take account of a minimum point in w near the cone surface. In contrast to two dimensional flow, this can be achieved by using polynomials to represent the normal gradient of w as a function of w , and square root factors, which seriously complicate the use of orthonormal M.I.R., are not needed. The extended calculation enables us to calculate the complete flow field over yawed supersonic cones, at different Mach numbers and yaw angles, including that in the far leeward region. (Reprints).

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Brain Research, v406 p 402-407 1987.

ABSTRACT: (U) Changes in the discharge rates of monkey primary somatosensory cortical neurons were recorded during the performance of wrist flexion and extension. Neurons with activity changes that occurred early before movement onset were often found in areas 3a, 1 and 2, but rarely in area 3b. Based on timing considerations, these observations suggest that somatosensory cortical neurons receive central as well as peripheral inputs that modulate their activity and that may be related to changes in tactile threshold before movement. Nerve transmission, Neurochemistry; Senses(Physiology); Contractions; Reprints.

ABSTRACT: (U) The stability bound for the classical nonlinear Euler beam is determined in the case that its deflection is limited by an obstacle parallel to the plane of the beam. Let a clamped or simply supported beam be axially compressed by a force $P > P_{sub 0}$ where $P_{sub 0}$ denotes the critical load. So far only a linear theory has been applied to analyze the stability of the solutions in contact with the obstacle and the jumping to a different state. Utilizing a free boundary problem formulation we analytically as well as numerically answer these questions for the nonlinear beam. Keywords: Structural beam deflections; Bifurcation(Mathematics). SUPPLEMENTARY NOTE: Pub. in Proceedings of the Conference on Numerical Methods in Fluid Dynamics (10th) p314-319, 23-27 Jun 86.

ABSTRACT: (U) The calculation of laminar boundary layer flow in two dimensions, using the Dorodnitsyn Method of Integral Relations, was successfully extended to separated regions. The extension requires incorporation of a square root term in the representation of the local shearing stress as a function of the streamwise velocity component. This limits the order of approximation that can be conveniently carried out for various flow configurations in plane flow and presents obstacles to the generalization of M.I.R. for three dimensional flow. The same difficulties arise in developing the orthonormal version of M.I.R. both for laminar and turbulent boundary layers. A recent paper treats laminar boundary layer flow in two dimensions by solving the Dorodnitsyn integral form of the equations of motion using a Finite Element Method. In the present paper this approach is extended to boundary layer flows dominated by positive pressure gradients. Free interaction couples the viscous and inviscid regions in which no iteration between these regions is required. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) Turbularization of an acoustic boundary layer (Stokes Layer) on impermeable and permeable surfaces is analytically considered. The theoretical approach uses a second-order closure model of turbulence. Both an approximate, closed-form solution and a more comprehensive finite difference solution of the time dependent, parabolic, one-dimensional governing equations are obtained. For simple acoustic boundary-layers on impermeable surfaces, both the approximate solution and the numerical results for the critical acoustic Mach number required for turbulent transition are qualitatively confirmed by experiment. Calculations for acoustic boundary-layers with transpiration (injection) indicate a substantial reduction of the acoustic Mach number required for transition, up to a limiting injection velocity that is frequency dependent. The results may provide a mechanism for flow-related combustion instability in practical systems, particularly solid propellant rockets, since turbularization of the near-surface combustion zone could result at relatively low acoustic Mach numbers. This report documents a completed phase of work which is concerned with the

ABSTRACT: (U) A remarkably simple, experimentally inspired, new theory of vision is presented. The theory takes into account the parallel architecture, the adaptive phenomena and the efferent control system which have been demonstrated in the vision systems of organisms. Further the complexities of visual receptive fields are made use of to explain the speed, noise resistance, consistencies and holistic aspects of perception. In this theory image understanding is achieved by image seeking adaptive networks that differentially amplify images of interest without first breaking them down into elementary components. A computer implementation of the theory demonstrates that the mechanisms postulated are feasible. A number of experiments with the model address critical aspects of image understanding and demonstrate that images of interest are captured reliably even in large amounts of noise, or in spite of position and/or size changes. Subjective edges, and other Gestalt like images, i.e. horizon and terrain are also seen by ISAN's basic network. Some implications for general vision are outlined.

ABSTRACT: (U) The interaction of a high speed (10-20 km/sec) plasma flow of modest temperature (0.5-5 eV) with a solid surface is a basic phenomenon in a variety of high specific power devices, such as advanced high specific impulse thrusters. Study of the details of processes involved in the immediate vicinity of the surface is normally precluded by the very limited diagnostic access afforded in mission-oriented devices. The present research program establishes a plasma flow by means of a quasi-steady magnetoplasmdynamic arcjet and exposes simple solid surfaces to this flow while examining the plasma surface interaction spectroscopically. Detailed measurements provide the benchmark for theoretical modeling that may then be applied to the more complex geometries of actual plasmadynamic devices. The present report covers the development and characterization of the arcjet plasma source and the initial results from experimental diagnostics focused near the surface of a dielectric blunt body in a high speed argon flow.

ABSTRACT: (U) The spectral representations for arbitrary discrete parameter infinitely divisible processes as well as for (centered) continuous parameter infinitely divisible processes, which are separable in probability, are obtained. The main tools used for the proofs are (I) a polar-factorization of an arbitrary Levy measure on a separable Hilbert space, and (II) the Wiener-type stochastic integrals of non-random functions relative to arbitrary infinitely divisible noise.

SUPPLEMENTARY NOTE: Pub. in International Conference on Acoustics, Speech and Signal Processing, p395-398 1987.

ABSTRACT: (U) A new approach to stability of adaptive filters is presented. The notion of constrained-input/constrained-output (CICO) stability is introduced as a generalization of the standard notion of bounded-input/bounded-output (BIBO) stability. This new notion involves a set of constraints on the filter data (i.e., signals and parameters) that, unlike boundedness, are specific to the filter in consideration. The set of all data that satisfy the constraints is the feasibility domain of the adaptive filter. Three particular adaptive lattice filters are analyzed: (i) Burg's lattice, (ii) the unnormalized RLS lattice, and (iii) the normalized RLS lattice. We derive the feasibility domains of these adaptive filters and prove that they are CICO stable.

ABSTRACT: (U) The research objective of this project is to study the estimation and control of elastic systems composed of beams and plates in order to develop efficient and accurate control and estimation algorithms. In the case of estimation basic to this goal is the development of an understanding of properties of the parameter to state mapping, an approximation theory associated with the particular models and minimization problems, and the suitability of different minimization algorithms for efficient codes for various problems. In control of prime importance is to determine properties of optimal controls and feedback, best location based on design of the actuators and the geometry and elastic properties of the body, and suitable algorithms and codes for control. Toward these objectives the work during the past year has centered primarily on the estimation and control of both static and dynamic linear models.

ABSTRACT: (U) Recently introduced lattice-filter configurations for processing of two-dimensional signal fields consist of multiple-input/multiple-output (4x4) memoryless sections with J-orthogonal chain-scattering matrices. In this paper we characterize all possible parametrizations of such lattice sections and we analyze in some details two particular implementations. Our analysis establishes a fundamental connection between the flexibility in implementing multiple-input/multiple-output lattice sections and the non-uniqueness of matrix square roots. Hermitian square roots lead to implementations with interesting analytical properties, while triangular square roots lead to computationally-efficient implementations. (Reprints)

ABSTRACT: (U) The precision of smooth pursuit eye
movements was described by means of a new dependent
measure, the 'oculomotor difference threshold' which
represents the smallest difference in target velocity
that produces statistically distinguishable differences
in eye velocity. Oculomotor difference thresholds for
constant velocity motions were largest during the initial
200 msec of target motion, despite fairly high average
gains during the same period. Oculomotor difference
thresholds declined over time. By about 600-700 msec
after the onset of target motion they reached values a
low as the perceptual difference thresholds measured
psychophysically with the same target velocities.
Nonsensory influences on smooth eye movement were also
found. Keywords: Eye movements; Smooth pursuit; Velocity
discrimination; Weber fraction; Difference threshold;

SUPPLEMENTARY NOTE: Pub. in AIAA Jnl., v25 n3 p401-407
Mar 87. Presented at AIAA Aerospace Sciences Meeting
(24th), Reno, NV, 6-9 Jan 86.

ABSTRACT: (U) A comparative study is made between the
MacCormack explicit-implicit predictor-corrector and the
Beam-Warming fully implicit algorithms for solving
compressible viscous flow. The mass-averaged, two-
dimensional compressible Navier-Stokes equations in
strong conservation law form and general curvilinear
coordinates are solved numerically by marching forth in
time on a body-fitted curvilinear grid for a shock-wave/
turbulent boundary-layer interaction over a two-
dimensional compression corner. Computations are
performed for a Mach number of 1.96 with a Reynolds
number Resub delta sub infinity (based on the incoming-
layer thickness delta sub infinity of 250,000 and for a
Mach number of 2.83 with a Reynolds number of 1,800,000.
The primary objectives of the study are 1) to determine
the extent to which the steady-state solution obtained by
the hybrid MacCormack algorithm is dependent upon the
size of the time step employed in marching the
calculation toward the steady-state solution, 2) to
compare the two algorithms regarding accuracy and
efficiency, and 3) to further examine the efficiency, and
3) to further examine the efficacy of the Baldwin-Lomax
algebraic turbulent eddy-viscosity model through
comparison with recent experimental measurements of the
Reynolds shear stress. (Author)

ABSTRACT: (U) Silicon Hydride has been identified as a
photolysis product in the infrared multiple photon
dissociation of RSiH₃ (R = n-butyl, phenyl), arising from
secondary IR MPD of silane produced in the initial four-
center elimination step. The radiative lifetimes of
levels show a strong rotational state dependence. The
infrared multiple photon dissociation (IR MPD) of
organosilanes has been observed to yield olefins, silane,
and a deposit of adjacent surfaces identified as
amorphous silicon (a-Si-H). The low silane olefin product
ratios found in those experiments, and the accompanying
deposition of a-Si-H, were attributed to secondary IR MPD
of the vibrationally hot silane produced in the initial
photolysis steps to yield silylene (SiH₂). In order to
verify this proposed mechanism, we have used laser
excited fluorescence (LIF) to detect the SiH₂ produced in
this reaction.

SUPPLEMENTARY NOTE: Pub. in Chemical Physics Letters, v138 n2-3 p276-282, 17 Jul 87.

ABSTRACT: (U) The first silanedilimine, N,N'-bis(trimethylsilyl) (Me₃SiN=Si=NSiMe₃) (5) has been photochemically generated from 2,2-diazo-hexamethyltrisilane (1) in hydro-carbon glasses at low temperatures. Photolysis of 1 at 254 nm leads first to the azido-silanimine Me₃SiSi (N₃)=NSiMe₃, lambda_{max} 274 nm, which undergoes further photolysis to produce 5. The silanedilimine has an absorption maximum at 324 nm (epsilon_{max} = 2130 + or - 260 M/cm) and reacts with Me₃SiOMe to give ((Me₃Si)₂N)₂Si(OMe)₂.

ABSTRACT: (U) Orbital alignment effects are investigated for an energy transfer process involving several competing pathways in the system Sr (5s8p1p1) + rare gases and H₂. Most of the cross sections to populate either (1) the combined 5s8p 3pJ and 4d5p 3F4 states or (2) the individual 4d5p 3F3 level show a marked preference for the perpendicular approach of the p orbital. However the cross section with He to populate the 3F3 state strongly favors the parallel orbital direction. Keywords: Alignment, Electronic energy transfer, Laser, Orbital effects, Strontium, Hydrogen.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Molecular Structure, v147 p383-388 1987.

ABSTRACT: (U) The authors consider various physical problems which may be formulated in terms of integral equations of the first kind, including the two-dimensional screen Neumann and Dirichlet problems in acoustics (and crack problems in elasticity). Sharp regularity results for the solutions are available for these problems. Proven is the convergence of the p-version for some Galerkin boundary element schemes based on the integral equation formulations. It is shown that the rate of convergence obtained by our method is twice that for the usual h-version.

ABSTRACT: (U) The geometric structure of C-CaF8SF4 has been determined by gas-phase electron diffraction. The five-membered ring has the twist form (C2 symmetry) with a puckering amplitude $q = 0.42$ (2). The following principle geometric parameters (ra values) with estimated uncertainties have been derived: (C-C)av = 1.541 (10), S-C = 1.896 (7), S-Fe = 1.558 (6), S-Fe = 1.594 (6) A, CSC = 90.0 (9), SCC = 109.1 (8), CCC = 106.5 (12), FaSfe = 90.5 (15) and FaSfe = 87.7 (29). Vibrational amplitudes for long non-bonded C...F and F...F distances indicate a high barrier to pseudorotation of the ring. Keywords: Gas phase electron diffraction, Conformational, Dynamic properties, Five membered rings, Rigid structure, High pseudorotation barrier.

UNCLASSIFIED REPORT

ABSTRACT: (U) A lot of work has been done towards the direction of developing communication protocols that determine how a single common resource can be efficiently shared by a large population of users. By now, it is well known that fixed assignment techniques are not appropriate for a system with large population of bursty users. In the latter case, random access protocols are more efficient and many of them have been suggested. Usually, the amount of information transmitted per time is of fixed length, called a packet. In most of the systems, time is divided into slots of length equal to the time needed for a packet transmission (slotted systems). The deployment of an ever increasing number of multi-user random access communication networks, Brought up the question of how packets whose destination is another network, should be handled. Thus, the issue of network interconnection or multi-hop packet transmission, arises, 3, 6, 7. The basic problem in analyzing the interconnected systems is that of characterizing the output process of a multi-user random access communication system; i.e., the departure process of the successfully transmitted packets.

ABSTRACT: (U) Contents: Finite Element Methods for the Ladyzhenskaya Model of Viscous Flow; Survey of Finite Element Methods for Incompressible Viscous Flows; Finite Element Methods for Hyperbolic Equations.

ABSTRACT: (U) Experimental measurements have been made and interpreted in acetylene/oxygen and benzene/oxygen/argon flames at 2.7 kPa, and an unburned flow velocity of 50 cm/s with the objective of evaluating the ionic mechanism of soot nucleation. This mechanism postulates that chemi-ions are precursors of soot and that the initial reactions in the soot and nucleation process are ion-molecule reactions in which molecular ions continually increase in size until they are neutralized by ion combination. Total ion profiles were determined by Langmuir probe; individual ion profiles were determined by Langmuir probe; individual ion profiles were determined by molecular ion sampling mass spectrometry up to about mass 800; temperature profiles were determined by radiation corrected thermocouples. It is demonstrated that the ion concentration is greater than the concentration of soot particles; and ions decay as soot is produced. In the acetylene/oxygen, the ion-molecule reaction rates are measured and compared with other measured and calculated rates. It is demonstrated that these rates are rapid at flame temperatures. Some major differences were found in the features of benzene and acetylene ion profiles that remain to be explained. The experiments are strongly supportive of the ion mechanism of soot formation in flames.

UNCLASSIFIED REPORT

ABSTRACT: (U) This research project is investigating strategies to pharmacologically manipulate the circadian sleep-wake cycle in order to control the timing of alert function and of sleep in altered work schedule environments. In the past year we have investigated the benzodiazepines, diazepam (in hamsters) and triazolam (in squirrel monkeys), and have derived a phase response curve for each. In optically-enucleated hamsters, however, consistent phase shifts were not obtained suggesting that diazepam acts on light information-conveying pathways. Biochemical receptor binding studies are defining the benzodiazepine receptor density in various brain regions. In addition, the characterization of the circadian and homeostatic components of sleep in the squirrel monkey during sleep deprivation studies is being conducted in preparation for pharmacological manipulation with benzodiazepines. Keywords: Mathematical modeling; Jet-lag.

ABSTRACT: (U) This report describes the progress made during the first year of an equipment grant which has provided a common computing environment for four laboratories conducting research in perception and cognition at the University of Minnesota. Research in the Cognitive Psychology Laboratory has shown that learning a procedural skill can occur in the absence of any declarative learning. Progress has also been made toward developing a computer simulation of this process. In the Visual Psychophysics Laboratory several image-enhancement algorithms have been developed as well as a psychophysical procedure for evaluating those algorithms. Research in the Auditory Psychophysics Laboratory has concentrated on developing a model of the detection and recognition of complex auditory signals by human observers. A subset of the model has been implemented as a computer simulation and several experiments have been completed to guide its future direction. In the Psycholinguistics Laboratory a computer model of text comprehension and recall has been constructed. Several experiments have been completed that confirm assumptions built into the model and show a good correspondence between its performance and that of human subjects.

ABSTRACT: (U) This paper considers the linear quadratic optimal control problem on infinite time interval for linear time-invariant systems define on Hilbert spaces. The optimal control is given by a feedback form in terms of solution p_i to the associated algebraic Riccati equation (ARE). A Ritz type approximation is used to obtain a sequence p_i sub n of finite dimensional approximations of the solution to ARE. A sufficient condition that shows N sub n converges strongly to p_i is obtained. Under this condition, we derive a formula which can be used to obtain rate of convergence of N sub n to p_i . We demonstrate and apply the results for the Galerkin approximation for parabolic systems and the averaging approximation for heredity differential systems. (Author)

ABSTRACT: (U) Several lattice forms and algorithms which constitute the immittance domain alternatives to the PARCOR lattice algorithm are presented. The immittance variables were shown to offer more efficient Levinson algorithms than the conventional scattering algorithms for both symmetric and Hermitian Toeplitz matrices. This paper presents the lattices associated with the new recursions and provides algorithms to determine their coefficients directly from the signal segments. The new lattices are of interest for speech processing as they offer a different parametrization and process real signal segments with only one multiplier and two adders per section. Complex signal segments require two adders per section. Stability conditions for the new parametrizations are also presented.

ABSTRACT: (U) The treatment of separation of laminar and turbulent boundary layers using an inviscid-viscous flow matching approach is reviewed. In two dimensions this approach has been thoroughly investigated and a number of numerical techniques have been tested successfully against experimental results. The approach was initiated in a series of pioneer papers (Crocco and Lees, J. Aero. Sci., 1952, Lees and Reeves, AIAA J. 1964, Catherall and Mangler, J. Fluid Mech., 1966) in which the original Prandtl boundary layer concept was modified. Traditionally, in airfoil calculations, for example, the value of the pressure appearing in the boundary layer equations was calculated from an inviscid flow calculation past the airfoil profile. In the modified approach the inviscid calculation is to be applied to a profile displaced outwards through a distance equal to the boundary layer displacement thickness.

ABSTRACT: (U) The computation of system reliability from component reliabilities presents a host of non-trivial problems for systems of varying sizes. These include the functional relationship between the time required to compute system reliability and system size. A second problem concerns how system reliability varies as component reliabilities vary. A third problem concerns how statistical errors in estimating component reliabilities affect the accuracy of the system reliability computation. This paper describes Monte Carlo techniques which provide useful answers to the first two problems and presents an analysis which establishes the potential seriousness of the third problem in practice.

UNCLASSIFIED REPORT

ABSTRACT: (U) A simple procedure is proposed to determine a sample size for estimating the mean weight of items in a problem of obtaining a batch of a large number of items. Suppose it is desired to obtain a large number N (sub s) of items for which individual counting is impractical, but one can demand a batch to weigh at least v units and hope that the number of items in the batch is close to the desired number N (sub s). If the items have mean weight θ , it is reasonable to have v equal to θN (sub s) when θ is known. When θ is unknown, one can take a sample of size n , not bigger than N (sub s), estimate θ by a good estimator $\hat{\theta}$ (sub n) and set v equal to $\hat{\theta} n$ (sub s). The proposed procedure determines the sample size to be the integer closest to $\hat{\theta} N$ (sub s), where $\hat{\theta}$ is a function of the cost coefficients if the coefficient of variation ρ is known. It is shown to be optimal in some sense. If ρ is unknown, a simple sequential procedure is proposed for which the average sample number is shown to be asymptotically equal to the optimal fixed sample size. When the weights are assumed to have a gamma distribution given θ and θ has a prior inverted gamma distribution, the optimal sample size in some sense can be found to be the nonnegative integer closest to $\hat{\theta} N$ (sub s).

ABSTRACT: (U) Based on randomly right-censored data, a smooth nonparametric estimator of the quantile function of the lifetime distribution is studied. The estimator is defined to be the solution $x_{sub n}(p)$ to $F_{sub n}(p) = 0$, where $F_{sub n}$ is the distribution function corresponding to a kernel estimator of the lifetime density. The strong consistency and asymptotic normality of $x_{sub n}(p)$ are shown. Some simulation results comparing this estimator with the product of the bandwidth required for computing $F_{sub n}$ is investigated using bootstrap methods. Illustrative examples are given. ABSTRACT: (U) We advance a coherent development of zero-crossing-based methods and theory appropriate for fast signal analysis. Quite a few ideas pertaining to zero-crossing counts found in the literature can be expressed and interpreted with the help of this more general setup. A central issue addressed in some detail is the fruitful connection which exists between zero-crossing counts and linear filtering. This connection is explored and interpreted with the help of a certain zero-crossing spectral representation, and is then applied in spectral analysis, detection, and discrimination. Zero-crossing counts in filtered time series are called higher order crossings. The theme of this work is that higher order crossings analysis provides a useful descriptive as well as an analytical tool that can in many respects match spectral analysis. To a great extent these two types of analysis are, in fact, equivalent, but each emphasizes a different point of view. Advantages offered by higher order crossings are great simplicity and a drastic data reduction. (Reprints)

ABSTRACT: (U) The measurements of the angular distribution of desorbing positive ions produced by electron impact desorption (ESDIAD) is of fundamental importance in understanding molecular structure in the chemisorbed layer. In this short review, two applications of ESDIAD to structural problems in the adsorbed layer will be described. Examples of strong chemisorption and weaker physical adsorption effects will be discussed. In addition, interactions between adsorbed species, leading to changes in bonding geometry will be described. The apparatus used for this work allows digitized acquisition of ion angular distributions in the absence of background effects due to soft X ray emission stimulated by electron impact. Keyword: Chemisorption physorption, Stepped surfaces, Cyclopentene, Surface electric field, Silver nickel.

ABSTRACT: (U) This paper presents studies of solid state polymerization aimed towards formulating a dynamic model of reactivity in the condensed phase. Phonon spectroscopy is successfully used to elucidate the mechanism of lattice control of the reaction. Novel concepts of phonon-assisted thermal and photochemical reactions are introduced, supported by experimental data. Non-linear laser spectroscopy is used to find the importance of biexcitonic processes in photopolymerization. Also, spectroscopic studies of reactions in Langmuir Blodgett films and at gas solid interface which produce ordered polymers are presented.

ABSTRACT: (U) Experiments have been carried out in a variable pressure flow facility with the objective of studying the structure of a co-flowing jet diffusion flame. The flow is visualized using an optical scheme which superimposes the luminous image of the flame on its Schlieren image. This gives a useful picture of the relationship between the bright, yellow-orange, soot-laden core flow and the edge of the surrounding hot gas envelope. A loudspeaker is used to force the central fuel jet at several frequencies. In the unforced flow and over most of the driving frequency range in the forced flow, a double structure is observed with two distinct wavelengths: a long wavelength associated with the luminous, buoyancy-driven core flow and a short wavelength associated with the shear-driven outer flow. Excitation at the proper frequency causes strong coupling to occur. In this case the core flow pinches off and the flame breaks up into a series of flamelets moving with a single wavelength.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper is concerned with periodic, laser-induced, chemical vapor deposition recently observed experimentally. In order to inquire further into this phenomenon, it is first necessary to find a simple means of calculating the plasmon field strength for relatively deep gratings. The Rayleigh hypothesis is assumed, and only p-polarized, normally incident light is considered. A closed-form equation for the plasmon field intensity is then derived. Also discussed is the behavior of the plasmon dispersion relation for a shallow grating, but for a complex dielectric constant where the imaginary part is not necessarily small. Keywords: Plasmons; Chemical vapor deposition; p-polarized light; Complex dielectric constant. (Reprints)

ABSTRACT: (U) The physical phenomena described by nonlinear partial differential equations have become at present the central theme of investigations by many researchers. A good understanding of most physical processes requires accounting for nonlinear effects and, consequently, methods for studying nonlinear equations have to be developed. Among nonlinear equations the Dirichlet problem for the Monge-Ampere equation is the model case for fully nonlinear equations.

UNCLASSIFIED REPORT

ABSTRACT: (U) The probability of error in a binary
symmetric channel with intersymbol interference and
additive noise is efficiently calculated by numerical
quadrature of a Laplace inversion integral along a
contour in the complex plane passing through a
saddlepoint of the integrand. For Gaussian noise a bound
is set on the truncation error incurred by necessarily
restricting the integration to a finite interval. The
probability of error resulting from cochannel
interference is calculated by a similar technique.

ABSTRACT: (U) Matching data from a bivariate population
is considered when observations are available only in the
form of a broken random sample. In other words, a random
sample of n pairs is drawn from the population but the
observed data consist of n observations on the second
component and the n observations on an unknown
permutation of the first component of the n pairs of data.
A maximum likelihood matching strategy is revisited. The
proportion of approximately correct matches (due to Yahav)
is used to evaluate the performance of the pairing
strategy as n approaches limit of infinity. The small
sample behavior of this proportion is studied via a Monte-
Carlo simulation in the special case of bivariate normal
parent population. Keywords: Asymptotic properties;
Statistical data; Tables(data).

UNCLASSIFIED REPORT

ABSTRACT: (U) The principle objective of this study is to identify and develop an understanding of the mechanisms whereby acoustic suppressants modify an acoustic wave. The experimental bases for the technical approach of this study is a Rijke burner which generates combustion oscillations. During the past year three major modifications were made to the Rijke burner to facilitate obtaining more reproducible data: (1) The cooling jacket was rebuilt to give better heat transfer characteristics, and a flowmeter was incorporated to allow a quantitative control of the cooling water flow. (2) A digital data acquisition system was interfaced with the burner to allow monitoring more variables, and to improve data reduction techniques. (3) A new damping device consisting of a butterfly valve and a sound absorbing cone below the burner was developed to allow greater damping. Acoustic growth rate data have been obtained at a nominal frequency of 1200 Hz varying the mass flow rate, the oxidizer/fuel ratio, and the relative amount of nitrogen. In all cases, the growth rate increases as the energy release rate (or temperature) increases. These data will now be compared to the previously developed model to better understand the physical mechanisms driving the acoustic oscillations. The model is also being modified to incorporate various submodels for different types of particulates. Keywords:

ABSTRACT: (U) This report describe procurements made under contract number AFOSR-85-0120, as part of the Department of Defense, University Research Instrumentation Program. The equipment purchased is in support of analysis and encoding of color motion imagery. Installation of all equipment has been completed and is functional, attached to a VAX 11/750 in the Department of Electrical Engineering and the Center for Computer Aided Engineering. The major expenditure was for a Gould IP8400 imaging system with high-speed (30 frames per second) color storage and display. This system is operated as a peripheral on the VAX 11/750 running UNIX. To support image processing tasks, a CDA Array Processor was also purchased and attached to the system bus. Finally, to aid in data presentation, a hard-copy print camera was purchased from NISE Corp. The equipment is presently being used for a variety of image processing tasks, both for still and moving images. Plans include doing computer vision research and interdisciplinary work with groups who need real-time display of imagery.

ABSTRACT: (U) This paper presents results on the
convergence and asymptotic agreement of a class of
asynchronous stochastic distributed algorithms which are
in general time-varying, memory-dependent, and not
necessarily associated with the optimization of a common
cost functional. It is shown that convergence and
agreement can be reached by distributed learning and
computation under a number of conditions, in which case a
separation of fast and slow parts of the algorithm is
possible, leading to a separation of the estimation part
from the main algorithms.

ABSTRACT: (U) Consider a class of suspensions of diffeomorphisms of the annulus as flows in the orientable 3-manifold $T^2 \times I$. Construct a knotholder or template that carries the set of periodic orbits of the flow. We define rotation numbers and show that any orbit of period q and rotation number p/q can be arranged as a positive braid on p strands. This yields existence and uniqueness results for families of resonant torus knots (p-brands that are (p,q)-torus knots of period $q > p$), which correspond to order-preserving (Birkhoff-) periodic orbits of the diffeomorphism. Show that all other q-periodic p-brands have higher genus, and establish bounds on the genera of such knots. Obtain existence and uniqueness results for a number of other, non-resonant, torus knots, including non-order-preserving $(q + s, q)$ -torus knots of rotation number 1. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) Work continues primarily in gas phase turbulent mixing and chemical reactions with extensions to compressible (supersonic) shear layers. In the gas phase shear layer work, investigations concentrate on subsonic shear layer free stream density ratio effects, and a design effort in support of the planned extension of the hydrogen-fluorine shear flow facility to supersonic flows. In jet flows, measurements of gas phase jet mixing, using laser Rayleigh scattering techniques developed for conserved scalar measurements down to diffusion space and time scales, are in progress. A first publication has just appeared on an experiment in which digital imaging of soot in turbulent flames was used to describe combustion flame sheets in methane flames. Analytical/computational modeling efforts included development of quantitative description of turbulent jet mixing and chemical reactions including finite Damkohler number effects; supersonic shear layer combustion studies of finite kinetic rate (Damkohler number) effects for H₂/F₂/NO and H₂/air systems; a new analytical model for turbulent shear layer mixing and chemical reactions; and extensions of hydrodynamic stability calculations to include Mach number effects in supersonic shear layers.

UNCLASSIFIED REPORT

ABSTRACT: (U) Wave propagation characteristics of large space structures (LSS) affect their performance, integrity and the ability to nondestructively assess their integrity. In this study, wave propagation characteristics of an aluminum 22-bay planar lattice structure are determined experimentally. Two ultrasonic piezoceramic longitudinal transducers are mounted at various locations on the structure. Wave measurements are obtained by injecting an impulsive load via the transmitting transducer and recording the response via the receiving transducer. The waves injected into the structure are longitudinal waves, transverse to the surface, although a complex stress distribution which may be described by directivity functions is actually realized. The impulsive loading signal has a broad frequency spectrum containing frequencies greater than 0.5MHz.

EVJ38K

ABSTRACT: (U) In a previous report, transfer matrices and joint coupling matrices are used to compute natural frequencies of vibration of a five-bay planar lattice structure. In this report, the problem of detecting damage in the five-bay planar lattice structure is considered. Seven different states of damage are assumed. Each damage state corresponds to a disconnected or partially disconnected joint in the lattice. Transfer matrices and joint coupling matrices are used to compute natural frequencies associated with each damage state. The natural frequencies computed for each damage state are significantly different from the natural frequencies of the undamaged lattice; for example, the frequencies of the first flexible mode of the damaged lattice are 26% to 83% lower than the frequency of the first flexible node of the undamaged lattice. The results presented here demonstrate that measurement of natural frequencies is a potentially useful method for detecting damage in lattice structures, at least, for the types of damage considered here. However, it is also shown here that measurement of natural frequencies alone is not sufficient, in general, to determine the location of damage within the lattice structure. Thus, measurement of natural frequencies should be regarded as only a part of a complete nondestructive evaluation method. After the results

ABSTRACT: (U) Existence and bifurcation theorems are obtained for homoclinic orbits in three dimensional flows that are perturbations of families of planar Hamiltonian systems. The perturbations may or may not depend explicitly on time. The results of periodic orbits of the preceding paper are related to the present homoclinic results, and to a periodically forced Duffing equation with weak feedback. Keywords: Bifurcation; Hamiltonian system; Homoclinic orbit; Perturbation theory; Mainikov method; Reprints.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Time Series Analysis,
v8 n1 p39-50 1987.

SUPPLEMENTARY NOTE: Pub. in Proceedings of the American
Control Conference, p502-505 1987.

ABSTRACT: (U) The axis-crossing counts in time series
and in its successive differences are called higher-order
crossings (HOC). Under the Gaussian assumption the
sequence of expected HOC is monotone increasing and
admits a spectral representation which establishes a
clear connection between HOC and the spectrum. In
particular the normalized number of axis-crossings (first
HOC) tend to admit values at or near a dominant frequency
in the spectrum. When the series is first lowpass
filtered, the resulting normalized HOC tend to 'visit'
true discrete frequencies on their way to the highest
frequency. If the successive differences are replaced by
successive summation, the resulting modified normalized
HOC converge monotonically to the lowest frequency in the
spectrum. Keywords: Dominant frequency; Highest frequency;
Spectral; Gaussian; Monotone sequence; Mathematical
filters; Reprints.

ABSTRACT: (U) A useful technique for determining a
linear feedback control law which stabilizes an uncertain
system is the Riccati Equation approach. It considers
systems with time varying uncertainty in the system
matrix and obtain the constant feedback gains for the
linear stabilizing controller in terms of the solution of
a Riccati equation. This technique is extended to include
problems with time varying uncertainty in the input
connection matrix. Several examples are included to
demonstrate the efficacy of this result. Keywords:
Uncertain systems; Stability; Robust control; Linear
control problems; Reprints.

ABSTRACT: (U) While bifurcation theory has developed rapidly in recent years, there appears to be a need for a tighter framework for the numerical analysis of bifurcation problems. This paper presents such a mathematical framework for the numerical study of the bifurcation phenomena associated with a parameter-dependent equation $F(z, \lambda) = 0$. The presentation draws from differential geometry and singularity theory and provides a basis for various numerical methods used to detect and compute certain types of bifurcation points. SUPPLEMENTARY NOTE: Revision of report dated 10 Dec 86.

ABSTRACT: (U) It is shown that any form of Search Rearrangement Backtracking (SRB) requires exponential time to verify the unsatisfiability of nearly all of a wide class of CNF boolean expressions. This result is based on an input model which generates n independent k -literal clauses from set of r boolean variables. We assume that k is fixed and n and r tend to infinity. The result holds if the limit as n approaches infinity of $n/r(n) = \lambda$, is fixed and $\lambda > \ln(2)/(1-2)$ to the $-k$ power). SRB requires superpolynomial time nearly always if λ is replaced by $\lambda(n) = o(n)$ to the $1/\ln$ in (n) power and the limit as n approaches infinity of $\lambda(n) = \infty$ (so the superpolynomial time result holds, for example if $\lambda(n) = (\ln(n))$ to the beta power where beta is any positive constant) These results apply to any form of the Davis-Putnam Procedure.

UNCLASSIFIED REPORT

ABSTRACT: (U) An experiment was performed to examine the unsteady aerodynamics of stall penetration at constant pitch rate and high Reynolds number, in an attempt to more accurately model conditions during aircraft post-stall maneuvers and during helicopter high speed forward flight. The model spanned the 8 ft wind tunnel and consisted of a 17.3 in. chord wing with a Sikorsky SSC-AQO airfoil section. Two forms of pitching motion were used: constant pitch rate ramps and sinusoidal oscillations. Ramp data were obtained for 36 test points at pitch rates between 0.001 and 0.020, Mach numbers between 0.2 and 0.4, and Reynolds numbers between 2 and 4 million. Sinusoidal data were obtained for an additional 9 conditions. The results demonstrate the influence of the leading edge stall vortex on the unsteady aerodynamic response during and after stall. The vortex-related unsteady increments to the lift, drag, and pitching moment increase with pitch rate; the maximum delta C sub L is 1.2 at A = 0.02. Angular delays in stall events also increase with pitch rate. Vortex strength and propagation velocity were determined from pressures induced on the airfoil surface. The vortex is strengthened by increasing the pitch rate, and is weakened both by increasing the Mach number and by starting the motion close to the

ABSTRACT: (U) The present authors have studied the scattering of electromagnetic waves using variational method. Thus, that the work can be regarded as an extension of the work Tai and Cassidy and Fairberg to include both finite conductivity and arbitrary angle of incidence. Differential scattering patterns are then computed, along with the scattering, absorption and extinction. These cross sections are obtained by integrating the normal component of the Poynting vector over the surface of the fiber, enabling us to avoid the integration over the far-field sphere usually employed to compute scattering. In addition, it is found that energy considerations are exactly satisfied: the extinction cross section, which by the optical theorem must equal the imaginary part of the forward amplitude, is identically equal to the sum of the absorption and scattering cross sections. This result is particularly valuable for those applications in which we study the scattering and absorption properties of the cloud of such fiber particles.

ABSTRACT: (U) The two research activities are included as two separate divisions of this research report. The research activities are as follows: 1. Adaptive Recursive Interpolated DPCM for image data compression (ARIDPCM). A consistent theme in the search supported under Grant Number AFOSR under Grant AFOSR-81-0170 has been novel methods of image data compression that are suitable for implementation by optical processing. Initial investigation led to the IDPCM method of image data compression. 2. Deblurring images through turbulent atmosphere. A common problem in astronomy is the imaging of astronomical fluctuations of the atmosphere. The microscale fluctuations limit the resolution of any object by ground-based telescope, the phenomenon of stars twinkling being the most commonly observed form of this degradation. This problem also has military significance in limiting the ground-based observation of satellites in earth orbit. As concerns about SDI arise, the observation of Soviet Satellites becomes more important, and this observation is limited by atmospheric turbulence.

ABSTRACT: (U) Given a random field belonging to some specific class, and given a data sample generated by the random field, the author considers the problem of finding a field of the given class that approximates the field that generated the sample. This paper derives a solution to this problem for the simple case of a field consisting of independent random variables. Subsequent papers will treat other types of fields, e.g., having Markov dependencies. Numerical examples are given, showing that good approximations can be obtained based on relatively small sample sizes. In particular, this approach can be used to find random field models that generate given samples of image texture, and so can be applied to texture classification or segmentation. Keywords: Stationary; Random variables; Markov Chains. (Author)

ABSTRACT: (U) This book contains most of the papers presented at the symposium: Materials for Infrared Detectors and Sources held in Boston, Massachusetts, December 1-5, 1986. This symposium brought together the leading groups from the USA, Europe and Japan working on the preparation and characterization of materials for infrared detectors and sources. Much of the activity in this field is driven by the need for focal-plane array imagers operating in the medium (3-8 micron) and long (8-14 micron) wavelength atmospheric transmission windows. In addition there is now a growing interest in the preparation and exploration of detector and source materials for fiber-optic communications at wavelengths beyond 1.5 microns. The objectives of the symposium were threefold: firstly, to review progress in the key areas of bulk and epitaxial growth technologies for preparation of infrared materials; secondly, to review techniques for characterization of infrared materials; and thirdly, to evaluate the potential of novel materials and structures

SUPPLEMENTARY NOTE: Pub. in Annual Asilomar Conference on Signals, Systems and Computers (20th), p1-5 Dec 86.

ABSTRACT: (U) In this paper, we propose a modified Capon beamformer to give improved performance in coherent jamming environments. First, we briefly discuss the interference rejection and signal cancellation properties of the Capon beamformer in the presence of correlated interference, with a view to motivating the need to decorrelate the desired source signal from the interferences. We then introduce subarray covariance averaging techniques for decorrelating the impinging sources, and present an optimal weighting scheme that ensures perfect decorrelation of the sources for any given number of subarrays. Computer simulations are included to support our analysis.

ABSTRACT: (U) In this reprint we the authors consider the problem of predicting where fill-in occurs in the orthogonal decomposition of sparse matrices using Householder transformations. It is shown that a static data structure can be used throughout the numerical computation, and that the Householder transformation can be saved explicitly in a compact format.

DESCRIPTORS: (U) *SPARSE MATRIX, COMPUTATIONS, DATA BASES, FORMATS, NUMERICAL METHODS AND PROCEDURES, ORTHOGONALITY, REDUCTION, REPRINTS, STATICS, DECOMPOSITION, TRANSFORMATIONS(MATHEMATICS), MATHEMATICAL PREDICTION.

IDENTIFIERS: (U) Householder transformations, PE81102F, WUAFOSR2304A3.

ABSTRACT: (U) A parallel algorithm is developed for Cholesky factorization on a shared-memory multiprocessor. The algorithm is based on self-scheduling of a pool of tasks. The subtasks in several variants of the basic elimination algorithm are analyzed for potential concurrency in terms of precedence relations, work profiles, and processor utilization. This analysis is supported by simulation results. The most promising variant, which we call column-Cholesky, is identified and implemented for the Denelcor HEP multiprocessor. Experimental results are given for this machine. Keywords: Reprints; Charts; Statistical data; Self-scheduling loops; Experimental data. (Author)

ABSTRACT: (U) In this paper we introduce a new adaptive array able to separate superimposed directional signals without requiring any a priori information. The new adaptive array combines bearing estimation and adaptive array processing. The suggested adaptive array utilizes a root-tracking algorithm that is based on Pisarenko's harmonic retrieval method which can handle correlated array input signals. (Reprints)

ABSTRACT: (U) A loglinear model for predicting magazine exposure distributions is developed and its' parameters are estimated by using the maximum likelihood technique. The accuracy of the loglinear and a Dirichlet-multinomial model are compared using 1985 AGB: McNair data. The result show that the loglinear model has significantly smaller prediction errors than the Dirichlet-multinomial model. A simple algorithm for optimal media scheduling is given. Keywords: Advertising; Statistical analysis; Efficiency. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) The Bayesian nonparametric approach to estimating the tolerance distribution in quantal bioassay has received some attention. The computational difficulty in evaluating these Bayes estimators has hindered their application. This paper explores the linear Bayes approach to the bioassay problem. These linear Bayes estimators can be computed easily by using statistical software which has the capability of inverting a matrix. Let us state the quantal bioassay problem as follows: The experimenter intends to test the potency of a stimulus by giving subjects injections of the stimulus at different levels; namely, he chooses L dosage levels, t sub $1, \dots, t$ sub L , and treats n sub $1, \dots, n$ sub L subjects at these levels respectively. Each subject possesses a fixed tolerance level. If a stimulus exceeds a subject's tolerance level, the subject responds positively. If not, there is no response. Therefore we observe the number of positive responses at each level. These numbers are denoted by k sub $1, \dots, k$ sub L . The potency curve F is the distribution of tolerance levels; i.e. F is defined by the probability $F(t)$ of getting a positive response to a dosage at level t for all t . The objective of this article is to make inferences about the potency curve F . Keywords: Ferguson's Dirichlet process.

ABSTRACT: (U) A multi user random access communication system with a population of two classes of users is considered. It is assumed that packets generated by users from different classes have different priorities. Fast moving users in a mobile communication system, or high priority users in a static environment, might be members of the high priority class. A binary feedback collision resolution algorithm is developed and both throughput and delay analysis are performed. Analytical results show that for the operation region of practical interest, the high priority class experiences significantly shorter delays, compared to the low priority one which maintains good delay characteristics. UNCLASSIFIED REPORT

ABSTRACT: (U) This paper develops an algebraic approach to the multiple time scale analysis of perturbed linear systems based on the examination of the Smith form of the system matrix viewed as a matrix over a ring of functions in the perturbation parameter. This perspective allows us to obtain a strengthened version of the results of an earlier work and to provide a bridge between these complex but general results and previous explicit, conceptually simple, but somewhat restrictive results. In addition, the authors' algebraic framework allows them to investigate a variety of other problems. In this paper they study the problem of developing valid time scale decompositions in cases in which weak damping terms discarded in the approaches in earlier works must be retained. Also, this approach exposes the role of the invariant factors of the system matrix in determining its time scales. This leads naturally to the problem of time scale modification, i.e., invariant factor placement, via state feedback. A result along these lines is presented.

ABSTRACT: (U) The exact likelihood of the data coming from a moving average model of order is complicated. In this paper, the authors propose a method of estimation of the parameters of a moving average model of order one based on the approximate likelihood of the data and on the simulation of a pair of random variables. Some comparisons were made of this method with some well known methods for moderate sample sizes. A computer program is appended which is helpful in using this methods. ABSTRACT: (U) This paper extends and generalizes to the multivariate set-up earlier investigations related to expected remaining life functions and general hazard measures including representations and stability theorems for arbitrary probability distributions in terms of these concepts. (Author)

ABSTRACT: (U) Suppose that X sub $1, \dots, X$ sub n are iid. samples drawn from a d -dimensional population with density function f . Let $f(x)$ sub $n = f$ sub n (x ; X sub $1, \dots, X$ sub n) be an estimator of $f(x)$. The Integrated Square Error (ISE) and Mean Integrated Square Error (MISE) of f sub n are important and widely used criteria in evaluating the performance of an estimator f sub n . Quite a lot of works appeared in the statistical literature dealing with the asymptotic properties of them, for various types of estimators, such as kernel estimator, orthogonal series estimator, nearest neighbor estimator, etc. This paper the authors describe the necessary and sufficient conditions for the histogram estimator.

UNCLASSIFIED REPORT

ABSTRACT: (U) Linear regression models are widely used in statistical analysis of experimental and observational data. Usually the linearity of the model is merely an assumption and cannot be taken for granted. In some planned experiments, repeated measurements on the dependent variable Y can be taken while the independent variable X is held fixed. In such cases standard analysis-of-variance technique can be employed to generate a test for linearity. In many applications, however, the independent variable is observed simultaneously with Y. That is to say, X, as well as Y, is a random variable. Under such circumstances the usual method for testing linearity cannot supply. This paper studies this problem in large-sample context. The authors propose a method to test the linearity hypothesis based on a grouping of the data. The critical value of test-statistic is determined so that the test has a prescribed level of significant alpha asymptotically as the sample size tends to infinity. The consistency of the test is established, and the asymptotic power is calculated when the distance (in some sense) between the true regression function and the space of linear functions tends to zero in some specific rate.

ABSTRACT: (U) In one-way random effects unbalanced model the locally best invariant test for the equality of the treatment effects is derived. Surprisingly, this is different from the widely used familiar F-test. In the balanced case, however the two tests coincide and represent the uniformly most powerful invariant tests. For two-way random effects and mixed effects balanced models, the uniformly most powerful invariant test for the equality of the treatment effects is derived both with and without interaction, and shown to be equivalent to the usual F-tests under fixed effects models. The optimum invariant tests derived here are shown not to depend on the assumption of normality. Different aspects of null, nonnull and optimality robustness of these tests (Kariya and Sinha, Annals of Statistics, 1985) are studied. In the unbalanced two-way models however unlike in the fixed effects model providing a UMPI test, both random and mixed effects models present a difficulty which is pointed out. Keywords: Multivariate analysis; Analysis of variance.

ABSTRACT: (U) The purpose of statistical analysis is 'to
extract all the information from observed data'. The
recorded data may have some defects such as recording
errors and outliers and the first task of a statistician
is to scrutinize or cross-examine the data for possible
defects and understand its special features. The next
step is the specification of a suitable stochastic model
for the data using prior information and cross-validation
techniques. On the basis of a chosen model, inferential
analysis is made, which comprises of estimation of
unknown parameters, tests of hypotheses, prediction of
future observations and decision making. Examining data
under different possible models is suggested as more
informative than using robust procedures to safeguard
against possible alternative models. Finally data
analysis must also provide information for raising new
questions and planning future investigations. Some
aspects of data analysis as outlined above are
illustrated through examples.

ABSTRACT: (U) In this paper, the authors consider the problem of change points using Gaussian process. The distribution of the statistic to estimate a change point constructed in this paper can be approximated by the first type of extrimal distribution. Based on this, detection and interval estimation of a change point in various situations are discussed. Keywords: Variance; Heuristic methods; Asymptotic normality.

ABSTRACT: (U) For multivariate distributions with finite second order moments, a nonparametric symmetric, unbiased estimator of the generalized variance is considered, and it is shown to be (nonparametric) optimal for the class of distributions having finite fourth order moments. A jackknifed version of the sample generalized variance is also considered as a contender; it is computationally more convenient and asymptotically equivalent to the former. It is also shown that the second estimator performs quite well (in large sample) relative to the optimal normal theory estimators under several loss functions. (Keywords: kernels; U-statistics; von mises' functionals).

ABSTRACT: (U) In this paper, the authors considered the problem of estimation of the frequencies and the number of signals under a signal processing model with multiple sinusoids. The frequencies are estimated with eigenvariation linear prediction method. The number of signals is estimated with an information theoretic criterion. The strong consistency of the estimates of the frequencies and the number of signals is also established. Also, a modification of forward backward linear prediction method is suggested to yield consistent estimators of the frequencies.

DESCRIPTORS: (U) *ESTIMATES, *LINEAR SYSTEMS, *PREDICTIONS, *SIGNAL, MODELS.

IDENTIFIERS: (U) PE61102F, WUAFOSR2304A5.

ABSTRACT: (U) This document considers the linear regression model $y_{sub i} = x_{sub i} B + e_{sub i}$, $i = 1, 2, \dots$, where $(x_{sub i})$ is a sequence of known p-vectors, $B = (Beta_{sub 1}, \dots, Beta_{sub p})$ is an unknown p-vector, known as regression coefficients, $(e_{sub i})$ is a sequence of random errors. It is of interest to test the hypothesis $H_{sub k}$: $Beta_{sub k+1} = \dots = Beta_{sub p} = 0$, $k = 0, 1, \dots, p$. We do not assume that the random errors are identically distributed and have zero means, since it is sometimes realistic. As a compensation for this relaxation, we assume the errors have a common bounded support $A_{sub 1}$, a $Sub 2$ under certain conditions, we obtain the strongly consistent estimate of the number k for which $Beta_{sub k}$ is not equal to 0 and $Beta_{sub k+1} = \dots = Beta_{sub p} = 0$, by using the information theoretical criteria.

DESCRIPTORS: (U) *VARIABLES, COEFFICIENTS, CONSISTENCY, ERRORS, HYPOTHESES, STATISTICAL INFERENCE, MULTIVARIATE ANALYSIS, MATHEMATICAL MODELS, REGRESSION ANALYSIS, SEQUENCES.

ABSTRACT: (U) In probability theory the following two measure theoretic problems are well known: 1) Marginal problem: for fixed probability measures (laws) P Sub 1 and P Sub 2 on a measurable space U and a measurable function c on the product space U Squared = $U \times U$: and 2) Moment problem: for fixed real numbers a sub ij and real-valued continuous functions f sub ij ($i = 1, 2, j = 1, \dots, n$). This paper is devoted to the explicit solutions of some moment problems on separable metric space U with metric d .

ABSTRACT: (U) Two-parameter point processes are studied in connection with martingale theory and with respect to the partial-order induced by the Cartesian coordinates of the plane. Point processes are characterized by jump stopping times and by their two-parameter compensators. Properties of the doubly stochastic Poisson process, as predictability, are discussed. A definition for the Palm measure of a two-parameter stationary point process is proposed.

ABSTRACT: (U) An 111-posed linear problem $Ax=y$ in Hilbert space is considered as a filtering problem $Ax+Z=y$ for Hilbert space valued random elements. Depending on the models for the signal X and the noise Z , the solutions of this problem are discussed in the context of cylinder measures on Hilbert spaces and their radification by the Abstract Wiener space concept. Extensions of the solutions to measurable transformations are given explicitly. The filtering solution is related to the solution of the problem $Ax=y$ obtained by Tichonov's regularization method.

ABSTRACT: (U) A short proof is given for Ito's result that the multiple Wiener integral can be written as an iterated stochastic integral, using the martingale property of Brownian motion and a simple property of symmetric tensor products of the L^2 squared - space. (Author)

ABSTRACT: (U) Let $(x(t))$ be a Markov process, not assumed to be time homogeneous. It is well known that $(s(t), \bar{x}(t)) = (t, X(t))$ is a time homogeneous Markov process. Let A be its generator. The Feynman-Kac's formula for $x(t)$ takes the following form if the equation: $(1,1) A v + c v = 0$ admits a solution v , then v has the representation, for $s < t$: $(1,2) v(s, X_s) = E v(t, X_t) \exp(\int_s^t c(u, X_u) du) \sigma(u, X_s)$. We prove this under general conditions on (X_t) .

ABSTRACT: (U) Let $X=(X_1, \dots, X_d)$ and $V=(V_1, \dots, V_d)$ be processes on $(0,1)$ or \mathbb{R}^+ , such that X is exchangeable while V_d is predictable. Under suitable conditions on X and V , the expression $E(p_1)$ Integral over j of $(V \text{ sub } j \text{ dX sub } j)$ will only depend on the marginal distributions of X and V . From statements of this type in discrete or continuous time, one may easily derive a variety of old and new results on predictable transformations which preserve the distribution of an exchangeable sequence or process. The same method yields a general result about reduction of continuous local martingales and marked point processes to independent Gaussian and Poisson random fields. Keywords: Stochastic Integrals; Product moments; Invariance in distribution; Levy processes; Martingales; Point processes; Brownian bridge; Random time changes.

ABSTRACT: (U) These lectures aim at giving an elementary
introduction to certain types of stochastic differential
equations in infinite dimensional spaces. One lecture
introduces countably Hilbertian Nuclear (CHN) spaces and
give some examples to illustrate why these infinite
dimensional spaces are convenient for the study of some
practical problems, e.g. those occurring in stochastic
evolutions. This lecture assumes a complete probability
space with a right continuous filtration. It also assumes
a given countably Hilbertian nuclear space. Ornstein-
Uhlenbeck stochastic differential equations on duals of
nuclear spaces introduces a special class of linear
stochastic differential equations with values in duals of
nuclear spaces, namely Ornstein-Uhlenbeck type processes
with a nuclear valued martingale as a driving term. Weak
Convergence of Solutions: now consider the weak
convergence of the solutions of to the corresponding
stochastic differential equations driven by a Gaussian
noise. This last lecture gives an outline of recent works
on stochastic evolution equations and nonlinear

ABSTRACT: (U) A-optimal and MV-optimal repeated measurements designs are given both for direct and residual treatment effects, for comparing several test treatments with a control. The model considered are basically of two types: without preperiods and the circular model. It is shown that some known balanced and strongly balanced uniform repeated measurements designs can be modified to obtain optimal designs for this problem. Some other methods of finding optimal designs are also given. Keywords: Experimental design; Problem solving.

Pub. in Chemical Physics Letters, v135 n1,2 p170-176, 27 Mar 87

ABSTRACT: (U) Experiments have been performed to obtain an understanding of the mechanism of Iodine monofluoride(B) production in the flames of fluorine atoms with various iodides. Measurements have been made of the relative IF(B), I(2P1/2) and I(2P3/2) concentrations in a F/Bismuth triiodide flame under various conditions, including the addition of oxygen (1 delta). The IF(B) vibrational state distributions from a wide range of F atom/iodide flames, both with and without the addition of metastable species such as O2(1 delta) and N(1 sigma), have a characteristic form, being Boltzmann for the lower vibrational levels but having an excess population for the higher levels. This striking similarity suggests a universal mechanism for IF(B) production. It is proposed that this involves the recombination of an excited iodine atom (2P1/2) with a ground-state fluorine atom. A kinetic model based on this proposal is shown to account for all the measurements. Keywords: Chemiluminescence, Laser fluorescence. (Reprints)

ABSTRACT: (U) A study of the spectroscopic and laser properties of the crystal erbium-and chromium-doped yttrium scandium gallium garnet (Er, Cr:YSGG) has been carried out. The absorption spectra from 300-1700 nm and the emission spectra in the regions around 800, 1600 and 2800 nm have been measured, along with the kinetics of emission and decay under pulsed excitation. Energy levels of the erbium ion have been determined. Analysis of the data shows that energy transfers from excited chromium ions to erbium ions with near-100% efficiency. The 2800-nm-region laser performance of Er,Cr:YSGG, under flashlamp pumping conditions has been observed and found to be superior in some aspects to other erbium-doped crystals. (Keywords: Lasers, Solid State, 2800 nm lasers, Erbium Doped).

EVJ38K

ABSTRACT: (U) If we are given a dynamic system with some built-in symmetry, should we expect periodic motions which somehow reflect this symmetry? And how would periodicity harmonize with symmetry? We are lead from dynamics to topology algebras, singularity theory, numerical analysis, and to some applications. A global point of view is one guiding theme along the way: we are mainly interested in periodic motions far from equilibrium. For a method we rely on bifurcation theory, on transversality theory, and on generic approximations. As a reward we encounter known local singularities. As a central new aspect we study the global interaction and interdependence of these local singularities, designing a homotopy invariant. As a result, we obtain an index 'H' which evaluates only information at stationary solutions. Nonzero 'H' implies global Hopf bifurcation of periodic solutions with certain symmetries. Putting it emphatically, 'H' harmonizes symmetry and periodicity. Curiously, 'H' need not be homotopy invariant.

ABSTRACT: (U) The main objectives of this research have been the development of smooth nonparametric estimators of quantile functions from right-censored data and the further study of smooth density estimators from censored observations. In particular, kernel type and generalized quantile estimators have been obtained under censoring which give better estimates of percentiles of the lifetime distribution than the usual product-limit quantile estimator. Other new results include the study of linear empirical Bayes estimators, prediction intervals for the inverse Gaussian distribution, nonparametric hazard rate estimation under censoring, nonparametric inference for step-stress accelerated life tests under censoring. Discrete failure models, reliability estimation when cause of failure is partially known, Gompertz failure models, simultaneous confidence intervals for pairwise differences of normal means, and optimal designs for comparing treatments with a control.

UNCLASSIFIED REPORT

ABSTRACT: (U) Two projects are described: (a) Stability criteria for difference approximations to hyperbolic systems, and multiplicity of matrix norms; and (b) Problems in applied and computational linear algebra. The aim of these projects was to achieve better understanding of useful computational techniques for hyperbolic initial-boundary value problems, and to improve basic mathematical tools often used in numerical analysis and applied mathematics.

DESCRIPTORS: (U) *FINITE DIFFERENCE THEORY, *LINEAR ALGEBRA, APPLIED MATHEMATICS, APPROXIMATION(MATHEMATICS), BOUNDARY VALUE PROBLEMS, COMPUTATIONS, HYPERBOLAS, MATHEMATICAL MODELS, NUMERICAL ANALYSIS, PARTIAL DIFFERENTIAL EQUATIONS, STABILITY.

IDENTIFIERS: (U) PE81102F, WUAFOSR2304A3.

ABSTRACT: (U) W.p.1. convergence results are obtained for stochastic recursive approximation algorithms under very general conditions. The gain sequence (a sub n) can go to zero very slowly and state-dependent noise, discontinuous dynamical equations and the projected or constrained algorithm are all treated. The basic technique is the theory of large deviations. Prior results obtained via this theory are extended in many directions. Keywords: Local linearization; Errors for tracking systems.

DESCRIPTORS: (U) *APPROXIMATION(MATHEMATICS), *CONVERGENCE, *STOCHASTIC PROCESSES, ALGORITHMS, DYNAMICS, EQUATIONS, GAIN, LINEARITY, RECURSIVE FUNCTIONS, SEQUENCES, THEORY, TRACKING.

IDENTIFIERS: (U) *Large deviations.

ABSTRACT: (U) Subjects first detected a target presented at the left of fixation, and then attempted to report, in order, the first four items (numerals or shapes) in a stream of items presented to the right of fixation. At comparably difficult presentation rates, 10/s for numerals and 5/s for shapes, reports showed a mixture of correctly ordered items with items reported in a direction opposite to their order of presentation. Reports fit a three-parameter attention-gating model (AGM), which assumes that (1) after target detection, an attention gate opens briefly to allow items to enter visual short-term memory (VSTM), and (2) report order is determined by the attention each item receives in VSTM. Items presented either early or late in the stream tend to receive less attention and are thus reported as later than more central items. The fit to the AGM for both numerals and unlabelled shapes provides evidence that reports reflect order in short-term visual (rather than verbal) memory.

DESCRIPTORS: (U) *ATTENTION, *MEMORY(PSYCHOLOGY), *VISUAL PERCEPTION, GATES(CIRCUITS), IMAGE PROCESSING, REPRINTS, SHAPE, SHORT RANGE(TIME), STREAMS, TARGET DETECTION, VISION.

UNCLASSIFIED REPORT

ABSTRACT: (U) The development of solution algorithms for complex flowfields have been the objective of this research. Embedded subdomains were used to resolve relevant physical processes in a global flow around aerodynamic bodies. Both non-adaptive and adaptive approaches were studied and developed. Results for solving the two dimensional Euler equations using non-adaptive and adaptive finite volume and finite element work are summarized. A new approach is reported for combining expert system approaches with adaptive procedural algorithms into a totally integrated methodology. Algorithms for adaptive explicit and non-adaptive semi-implicit Navier-Stokes calculations are reported. Recent results on formulation of outflow boundary conditions for the Navier-Stokes equations are also presented. Keywords: Euler equations; Navier Stokes equations; Finite element methods; Embedded grids; Adaptive grids; Computational fluid dynamics.

DESCRIPTORS: (U) *FINITE ELEMENT ANALYSIS, *FLOW FIELDS, ADAPTIVE SYSTEMS, AERODYNAMICS, ALGORITHMS, BOUNDARIES, COMPUTATIONS, DIFFERENTIAL EQUATIONS, EMBEDDING, FLOW, FLUID DYNAMICS, GLOBAL, GRIDS, INTEGRATED SYSTEMS, METHODOLOGY, NAVIER STOKES EQUATIONS, NUMERICAL METHODS AND PROCEDURES, SOLUTIONS(GENERAL), TWO DIMENSIONAL.

SUPPLEMENTARY NOTE: Pub. in Jnl. of the American
Statistical Association, v81 n393 p91-95 Mar 86.

ABSTRACT: (U) The authors introduce a new better than
used of age t sub o (NBU t sub o) class of life
distributions, where the survival probability at age 0 is
greater than or equal to the conditional survival
probability at specified age t sub o > 0 . The dual class
of new worse than used of age t sub o (NWU) - t sub o)
life distributions is obtained by reversing the direction
of inequality. In Section 3 the authors propose a test of
the null hypothesis that a new item has stochastically
the same residual life length than does a used item of
age t sub o . In Section 4 Pitman's asymptotic relative
efficiency is used to study large-sample power properties
of the test. (Author)

ABSTRACT: (U) Observers matched patches (simulated Munsell papers) in two simultaneously presented computer-controlled displays, a standard array presented under 6500-K illumination and a test array under 4000 or 10,000 K. Adaptation to the test illuminants was limited. The adjusted patch was surrounded by a single color (annulus display) or by many colors (Mondrian display). Observers either matched hue and saturation or made surface-color (paper) matches in which the subject was asked to make the test patch look as if it were cut from the same piece of paper as the standard patch. For two of the three subjects, the paper matches were approximately color constant. The hue-saturation matches showed little color constancy. Moreover, the illumination difference between the two displays was always visible. Our data show that simultaneous mechanisms alone (e.g., simultaneous color contrast) alter hues and saturations too little to produce hue constancy.

SUPPLEMENTARY NOTE: Pub. in SIAM Jnl. of Applied Mathematics, v47 n3 p643-661 Jun 87.

ABSTRACT: (U) Systems with wide bandwidth noise inputs are a common occurrence in stochastic control and communication theory and elsewhere, e.g., tracking or synchronization systems such as phase locked loops (PLL). One is often interested in calculating such quantities as the probability of escape from a desired error set, in some time interval, or the mean time for such escape. Diffusion approximations (the system obtained in the limit bandwidth as the approaches limit of infinity) are often used for this since they are easier to analyze. When the noise effects in the physical system are small, one is tempted to do an asymptotic analysis (noise intensity approaches limit of 0) on the diffusion approximation, and use this for the desired estimates on the original system. Such a procedure does not work in general: the double limit bandwidth approaches limit of infinity, intensity approaches limit of 0 is not always justified. Under quite broad conditions on the noise processes, it is justified for the systems studied here. We study a particular form of the PLL owing to the great practical importance of the system and because it provides a useful vehicle for understanding the extent of validity of the asymptotic methods for such systems. The basic analytical techniques are from the theory of large deviations. One seeks information on the escape probabilities, mean times, and on the most likely exit paths and exit locations. Also, we seek information on the interactions between the signals to be tracked and

AD-A185 768

the noise which are most likely to lead to exit. The large deviations technique is eminently suited to this job. (Reprints)

ABSTRACT: (U) This report summarizes the activities in support of the Air Force Research Project AFOSR-83-0255 during the past year. Efforts have been made to develop, test and analyze new fast techniques in matrix analysis for structural computations and least squares problems. Applications of this work include structural design and dynamics, and least squares filtering in signal processing. Implementations and tests have been made on modern high performance architectures such as the Cray X-MP, Alliant FX/8, Sequent Balance and the Intel iPSC Hypercube. Our recent work on parallel algorithms for near real-time signal processing computations has led to especially significant results. Keywords: Abstracts; Numerical linear; Algebra; Parallel processing; Signal processing. Structural optimization. (Author)

ABSTRACT: (U) The starting point of this investigation is the properties of restricted quadratic forms, x (Transposed) Ax , x an element of S a subset of R superscript m where A is an $m \times m$ real symmetric matrix, and S is a subspace. The index theory of Hestenes (1951) and Maddocks (1985) that treats the more general Hilbert space version of this problem is first specialized to the finite dimensional context, and appropriate extensions, valid only in finite dimensions, are made. The theory is then applied to obtain various inertia theorems for matrices and positivity tests for quadratic forms. Expressions for the inertias of divers symmetrically partitioned matrices are described. In particular, an inertia theorem for the generalized Schur complement is given. The investigation recovers, links and extends several, formerly disparate, results in the general area of inertia theorems. (Author)

ABSTRACT: (U) The effects of a wavy wall boundary on the stability of a laminar boundary layer was studied analytically. It was found that Tollmien-Schlichting waves are not excited by the wavy boundary. Only standing waves are produced. A generalization of non-parallel stability formulations was developed for application to any two-dimensional free shear layer.

SUPPLEMENTARY NOTE: Supersedes report dated 1 Mar 86, AD-
A183 222.

ABSTRACT: (U) This project initiated various aspects of
an ongoing study of numerical/analytic techniques for the
identification of periodic solutions to functional
differential equations. The techniques developed apply to
very general classes of equations, and have been
implemented on a variety of specific model problems.
Local techniques refer to methods that apply to the
problem of analyzing the Hopf bifurcation structure of
small periodic orbits of multiparameter systems. A
FORTRAN code, BIFDE, was written to analyze generic
bifurcations of general systems with infinite delay.
Global tracking methods have been developed to study the
growth and parameter dependence of global Hopf
bifurcations. Investigations have centered on the
development of spine-based approximation techniques and
their implementation in a FORTRAN code FDETRAK. Keywords:
Mathematical programming, Machine coding; Subroutines,
Numerical analysis.

SUPPLEMENTARY NOTE: Pub. in Wave Motion, v8 p429-443 1987.

ABSTRACT: (U) The behavior at caustics is analyzed for weakly nonlinear wave solutions of hyperbolic equations. It is shown that short waves, weak enough to be governed by linear or weakly nonlinear geometrical optics away from caustics, are governed by linear theory at and near caustics. For somewhat stronger waves, for which linear theory does not suffice at caustics, a weakly nonlinear caustic theory is developed. It leads to an equation derived by Guiraud, Hayes, and Seibass for gas dynamics.

ABSTRACT: (U) The research conducted under this contract focused on the molecular mechanics of polymeric films in relation to their ultrastructure and nonlinear optical properties aimed towards eventual applications in integrated optical and microelectronic devices. Several landmark results were obtained. They are: (i) First demonstrate of femtosecond of response of nonresonant optical nonlinearity in conjugated polymers. (ii) First demonstration of third-harmonic generation from monolayer film of a conjugated polymer. (iii) First case of a conformational transition in a monolayer film of a conjugated polymer. (iv) First picosecond coherent Raman scattering study of a polymeric system. Our studies of third order optical nonlinearities using picosecond and subpicosecond degenerate four wave mixing as well as third harmonic degeneration established clearly a strong dependence of $\chi(3)$ on the effective pie-electron conjugation. Our study of vibrationally resonance enhanced nonlinearity using coherent Raman scattering revealed an enhancement by two orders of magnitude with response still in picoseconds. The Langmuir-Blodgett method was applied for the preparation of monolayer and multilayer films of several types of polydiacetylenes. Our study showed that the Langmuir-Blodgett technique can successfully be used for molecular engineering of ultrathin polymeric films with monomolecular control. Other techniques used for the preparation of ultrathin

ABSTRACT: (U) For an undirected network $G=(V,E)$ whose arcs are subject to random failure, we present a relatively complete and comprehensive description of a general class of Monte Carlo sampling plans for estimating $g(s,T)$, the probability that a specified node s is connected to all nodes in a node set T . We also provide procedures for implementing these plans. Each plan uses known lower and upper bounds B , A on g to procedure an estimator of g that has a smaller variance $(A-g)(g-B)/K$ on K independent replications than that obtained for crude Monte Carlo sampling $(B-D, A=1)$. We describe worst-case bounds on sample sizes K , in terms of B and A , for meeting absolute and relative error criteria. We also give the worst-case bound on the amount of variance reduction that can be expected when compared with crude Monte Carlo sampling. Two plans are studied in detail for the case $T=t$. An example illustrates the variance reductions achievable with these plans. We also give the worst-case bound s on the amount of variance reduction that can be expected when compared with crude Monte Carlo sampling. Two plans are studied in detail for the case $T = t$. An example illustrates the variance reductions achievable with these plans. We also show how to assess the credibility that a specified error criterion for g is met as the Monte Carlo experiment

UNCLASSIFIED REPORT

ABSTRACT: (U) This technical program constitutes a theoretical research investigation of the kinetic mechanisms of negative ion information in plasmas. This study was directed toward elucidating the mechanisms of the most important volume-dependent reactions that occur in hydrogen-ion H-(D-) source devices, primarily of the Belchenko-Dimov-Dudnikov (BDD) type and toward evaluating other light negative anions, such as Li-, as possible sources. The primary goal of this research program was to identify the most important reactions leading to negative ion production or destruction and to estimate these reactions rates as a function of system parameters such as density, composition and temperature. A further goal was to explore new chemical sources for the production of light mass negative atomic ions. The results of this program furnish data and provide direction for more detailed investigations into the kinetics of both gas phase and gas-surface reaction rates of importance in ion source devices and provide input for reliable modeling of such systems. This investigation was carried out using quantum mechanical methods. Both ab initio and density functional approaches were employed in these studies.

ABSTRACT: (U) The quantum yields for production of I(2p_{3/2}) and I(2p_{1/2}) at 248 nm are reported for a variety of alkyl and substituted-alkyl iodides using the technique of two-photon atomic laser-induced fluorescence. These results are combined with those of others to provide quantum yields over a wide range of radical sizes, structures and substitutions. A model which incorporates impulsive energy disposal for the dissociation followed by a Landau-Zener description of the 300-101 curve crossing gives a good description of the Psi values. SUPPLEMENTARY NOTE: Pub. in Jnl. of Materials Science, v22 p1008-1011, 1987.

ABSTRACT: (U) In this study the material damping of laminated composites is derived analytically. The derivation is based on the classical lamination theory in which there are eighteen material constants in the constitutive equations of laminated composites. Six of them are the extensional stiffness designated by A, B, and D, the coupling stiffness designated by B and the remaining six are the flexural stiffness designated by D. The derivation of damping of A, B, and D is achieved by first expressing A, B and D in terms of the stiffness matrix Q(k) and h_k of each lamina and then using the relations of Q_{ij}(k) in terms of the four basic engineering constants E_L, E_T, G_{LT}, and ν_{LT}. Next we apply elastic and viscoelastic correspondence principle by replacing E_L, E_T... by corresponding complex modulus E*_L, E*_T..., and A by A*, B by B* and D by D* and then equate the real parts and the imaginary parts respectively. Thus we have expressed A_{ij}, B_{ij}, and D_{ij}, and D_{ij}, in terms of the material damping N(k)_L and N(k)_T... of each lamina.

ABSTRACT: (U) Trapped energy modes in the piezoelectric thin film on semiconductor composite resonator are explained and contrasted with modes that do not trap energy. The results of calculations of the quality factor of the fundamental essentially thickness-extensional mode in the composite resonator due to radiation into the bulk semiconductor wafer are discussed. The combination of materials considered was aluminum-nitride on gallium-arsenide. The calculations show that when trapping is not present the quality factor is a very rapidly varying function of the ratio of the composite resonator thickness to the wafer thickness and that the range of variation is very large, i.e., between one and two orders of magnitude. The calculations also reveal that when trapping is present the quality factor is always much larger and its range of variation with thickness ratio much smaller than when trapping is not present. The direct calculation procedure is required to check the accuracy of a perturbation procedure. The perturbation procedure for the calculation of the quality factor of the composite resonator due to radiation into the semiconductor wafer is discussed. The perturbation procedure enables calculations for the case of rectangular electrodes and diaphragms to be performed.

ABSTRACT: (U) A multi-element research program was conducted to improve understanding of the role of cascade losses in compressor post-stall behavior. Experiments in a special wind tunnel designed for high-angle-of-attack investigations included surface and smoke flow visualizations and hot film anemometer velocity measurements. Results showed the details of the stall development in a cascade, and the effect of stagger on measured flow losses. Predictions of a Navier-Stokes model for separated cascade flows were compared with experimental results. An improved compressor stage model predicts post-stall characteristics, and illustrates the application of the results to compression system analysis. UNCLASSIFIED REPORT

ABSTRACT: (U) The funded project was designed, initially to explore the effects of hydrazines upon cyclic nucleotide regulated neuronal processes. Cyclase as it was discovered that hydrazines were potent activators of this enzyme. In order to understand hydrazine actions in the CNS, it was required that more basic knowledge of the adenylyate cyclase cascade be accumulated and this study probed some of the distinctions between neural and non-neural adenylyate cyclase with that in mind. Specifically, the following has been accomplished during the project period: Interactions between the cytoskeleton and synaptic membrane adenylyate cyclase have been probed and we have found a reversible attachment between the GTP-binding proteins regulating adenylyate cyclase and that membrane. We have discovered that GTP binding proteins directly interact and may exchange nucleotide with one another, and have hypothesized this mechanism as an intracellular regulator of signal transduction. We have discovered a novel, neural GTP binding protein and are in the process of purification and characterization. We have devised a method for measuring adenylyate cyclase in monolayers of permeable cells and have used this method to explore the coupling between receptors and adenylyate cyclase GTP-binding proteins. It is hoped that an increased understanding of the neuronal adenylyate cyclase

ABSTRACT: (U) Visible chemiluminescence in the region 200-800 nm was measured for the reactions of Fluorine atoms with methane, methyl iodide, CD3I, CH2I2, CHI3 and CI4 studied at reduced pressure (ca. 0.8 mbar). Emission was observed from electronically excited IF (B), HCF (A), CH (A) and C2 (d) and from vibrationally excited HF. Vibrational populations and rotational temperatures were obtained for the diatomic emitters. The reaction F + CI4 was found to produce IF (B) with a non-thermal vibrational population distribution that has excess population in the higher vibrational levels. Possible mechanisms for the formation of the emitters are discussed. Keywords: Chemiluminescence, Iodine monofluoride, Organic Iodides.

ABSTRACT: (U) Diversity of bugs or faults in a software system is a factor contributing to software unreliability which has not yet been appropriately emphasized. This paper is written with the intention of demonstrating the impact of fault diversity on the time to detection of software bugs. A new discrete software reliability model based on the multinomial distribution is introduced. It is shown that for models of this type, the more diverse the fault probabilities are, the longer it takes to detect or eliminate any n faults, while the smaller will be the number of faults detected or eliminated during a given amount of time (or during a given number of inputs to the system). The impact of fault diversity is also demonstrated for the Jelinski-Moranda model. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This document considers a linear regression model, where $(x \text{ sub } i)$ is a sequence of experimental points, $i = 1, \dots, n$, known p -vectors, $(e \text{ sub } i)$ is a sequence of independent random errors, with $\text{med}(e \text{ sub } i) = 0$, $i = 1, 2, \dots$. Define the minimum L1 -norm estimate of $(\alpha, \beta)'$, by $(\alpha, \beta)'$, to be chosen such that under quite general conditions on $(x \text{ sub } i)$ and $(e \text{ sub } i)$, the strong consistency of the minimum L1 -norm estimate is established. Further, under an additional condition on $(x \text{ sub } i)$, it is also proved that for any given $\epsilon > 0$, there exist constant $C > 0$ not depending on n .

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on
Reliability, VR-35 n4 p419-422 Oct 88.

ABSTRACT: (U) Much of the recent work on modeling repairable systems involves Poisson processes with nonconstant intensity functions, viz, nonhomogeneous Poisson processes. Since times between failures are not identically distributed when the process is nonhomogeneous, it is not clear what concept should take the place of the mean time between failures in assessing the reliability of a repairable system. A number of alternate concepts can be found in the literature. We investigate the relationship between two of the most frequently considered alternatives; the reciprocal of the intensity function, and the mean waiting time from i until the next failure. Theorem 1 states a necessary and sufficient condition for the mean time until the next failure to be asymptotically proportional to the reciprocal of the intensity function. Some examples, including the familiar log-linear and power-intensity processes satisfy this condition. A monotonicity property is also established between these two concepts which could be used to obtain conservative statistical confidence limits for the mean time until the next failure, based on results which are already available for the intensity function of the power-intensity process. However, further study of concepts such as the rate of convergence would be needed in order to determine the

degree of approximation of the nominal confidence level to the actual level. Until more is known about the mean time from t until the next failure, it would be advisable to use the reciprocal of the intensity function, which has been studied more extensively, as the basis of reliability assessment for a repairable system. UNCLASSIFIED REPORT

ABSTRACT: (U) Two necessary components of any image understanding system are on object recognizer and a symbolic scene representation. The LandScan system currently being designed is a query driven scene analyzer in which the user's natural language queries will focus the analysis to pertinent regions of the scene. This is different than many image understanding systems which present a symbolic description of the entire scene regardless of what portions of that picture are actually of interest. In order to facilitate such a focussing strategy, the high level analysis which includes reasoning and recognition must proceed using a top-down flow of control, and the representation must reflect the current sector of interest. In order to facilitate such a focussing strategy, the high level analysis which includes reasoning and recognition must proceed using a top-down flow of control, and the representation must reflect the current sector of interest. This paper proposes the design for a goal-oriented object recognizer and a dynamic scene representation for LandScan a system to analyze aerial photographs of urban scenes. The recognizer is an ATN in which the grammar describes sequence of primitives which define objects. The Scene

ABSTRACT: (U) Conceptual designs of potentially attractive high-performance thrusters are defined. These are a kv steady-state radiation-cooled DC thruster and a MW quasi-steady DC thruster. These thrusters offer the potential for long operating life with low erosion rates and 50 to 100% improvements in performance over prior plasma thrusters. The kv thruster would be a prototype of a radiation-cooled electric thruster for future electric propulsion missions. The MW thruster would be an inexpensive experiment to define the potential of subsequent very-high power, steady-state thrusters which would utilize superconducting magnets. The kv thruster would use xenon propellant and the MW thruster would use argon propellant. Both should operate at efficiencies of 50 to 80% in the 2500 to 3000 second specific impulse range. Keywords include: Electric propulsion; Plasma, Electrothermal, and MPD thrusters.

ABSTRACT: (U) The Optical Transistor and Switch, for which concepts and designs were developed under this program, is a device in which a radiation beam of one wavelength is controlled by a beam of a second wavelength. In contrast to other optical transistors and switches, this arrangement keeps the requirements for control and signal independent and thus adds another dimension to design. The basic device provides simply an optical path through a medium which consists of free three-energy level atoms such as sodium vapor at very low pressures. It provides, with relatively low optical powers, satisfactory switching action and transistor saturation gains of 3-10. A subsequent concept is that of Multistate Optical Transistors based on spectroscopically complementary materials. Very high transistor gains can be achieved with two variations of this concept. However, the higher optical power demand and the stringent requirement of double resonance between two materials are important drawbacks. The third concept is the Quantum Transition Etalon which consists of a Fabry-Perot cavity enclosing the three-level medium. The QTE appears to have substantially the advantages of the two former concepts.

UNCLASSIFIED REPORT

ABSTRACT: (U) Experimental and theoretical efforts aimed at clarifying and revealing important dynamical features of several turbulent shear flows are described. The flows studied include boundary layers, jets, wakes and separated flows on lifting surfaces. Significant progress has been made through experimental studies toward understanding: (i) processes in turbulent boundary layers responsible for the production of turbulent energy via local, inflectional-instability events and the modification of boundary layer growth and entrainment by passive large-eddy manipulation devices; (ii) procedures for enhancing entrainment and mixing in jets either by actively forcing the flow or by passively contouring the jet exit; and (iii) characteristics of boundary layer separation and its control on lifting surfaces in unsteady flows. Theoretical studies on the temporal and spatial structure in blunt-body wakes have revealed the necessary conditions under which global, self-sustained oscillations appear and, also, have provided firm criteria for specifying the frequency of these oscillations. The results are consistent with existing experimental evidence and suggest promising approaches for drag modifications for flow over bluff bodies. Several experimental facilities have been designed. Keywords: Separated flows; Unsteady flows; Turbulent

Applications, V87 p273-278 1987.

ABSTRACT: (U) Few parts of applications-oriented mathematics have benefited from the interaction with modern algebraic and analytic geometry as much as the area usually referred to as multidimensional systems theory. This field consists of the study of various topics in the theory of functions of several complex variables, motivated mostly by problems in network design and synthesis and by signal-processing applications. Because of finite realizability constraints, the focus is often on rational functions; this accounts for the strong algebraic flavor of papers in the area, and in particular the use of techniques and results from commutative algebra. A linear-algebraic component is introduced by the need to consider matrices whose entries are analytic or rational functions. Multidimensional systems appear when dealing instead with partial differential (or difference) equations. The independent variables may now represent different space coordinates (as in image processing applications), or perhaps mixed time and space variables (as in seismic data processing). Multidimensional models are also useful when studying certain types of functional differential equations in one independent variable, as delay-differential systems.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper examines multivariate nonparametric classes and methods in reliability. Hollander and Proschan (1984) described the various univariate nonparametric classes in reliability. The classes of adverse aging described include the IFR, IFRA, NBU, NBUE, and DMRL classes. The dual classes of beneficial aging are also covered. Several new univariate classes have been introduced since that time. One that this document briefly mentions is the HNBUE class, since we are aware of several multivariate generalizations of this class. The univariate classes in reliability are important in applications concerning systems where the components can be assumed to be independent. In this case the components are often assumed to experience wearout or beneficial aging of a similar type. For example, it is often reasonable to assume that components have an increasing failure rate (IFR). In making this IFR assumption it is implicit that each component separately experiences wear and no interactions among components can occur. However in many realistic situations, adverse wear on one component will promulgate adverse wear on other components. From another point of view a common environment will cause components to behave similarly. In either situation, it is clear that an assumption of independence on the components would be valid.

ABSTRACT: (U) An algebraic structure underlying network reliability problems is presented for determining the 2-terminal reliability of directed networks. An iterative algorithm is derived from this algebraic perspective to solve the (s, j) -terminal reliability problem simultaneously for all nodes j . In addition to providing an exact answer (in the form of a reliability polynomial), the algorithm also yields a nondecreasing sequence of approximate solutions guaranteed to be lower bounds on the exact solution. Empirical results, presented for two different implementations of the algorithm, show that useful approximate solutions can be obtained in a reasonable amount of computation time.

ABSTRACT: (U) The Authors' primary aim is to build versions of generalized Gaussian processes from simple, elementary components in such a way that as many as possible of the esoteric properties of these elusive objects become intuitive. For generalized Gaussian processes, or fields, indexed by smooth functions or measures on IR sub d, our building blocks will be simple Markov processes whose state space is IR sub d. Roughly speaking, by summing functions of the local times of the Markov processes the Gaussian field shall be obtained via a central limit theorem type of result. This central limit result, together with related results indicating how additive functionals of the Markov processes generate additive functionals of the fields, yield considerable insight into properties of generalized Gaussian processes such as Markovianess, self-similarity, locality, of functionals, etc. Although the paper is comprised primarily of new results, and despite the fact that the subject matter is somewhat esoteric, our aims are primarily didactic and expository - we want to try to initiate the uninited into some of the mysteries of generalized processes via an easily understood model.

ABSTRACT: (U) The Brownian path $(\omega(s); 0 \leq s \leq t)$ is dissected and then reassembled in such a way that (1) the last visit $\gamma_{\omega}(t)$ at the origin, as well as the fragment $(\omega(s); \gamma_{\omega}(t) \leq s \leq t)$, are left invariant; (2) on $[0, \gamma_{\omega}(t)]$, local time becomes maximum-to-date and occupation time of I_R sub + becomes location of maximum; and (3) the resulting process is again Brownian. Characterization of conditional processes are employed to establish the result. Several consequences of the latter are discussed. Keywords: Brown motion; Continuous functions, Uniform convergence). UNCLASSIFIED REPORT

ABSTRACT: (U) This project explored fast algorithms for Euler and Navier Stokes simulations. A particular issue pursued under the grant was the integration of an explicit three dimensional flow solver, embedded mesh refinements, a model equation hierarchy, multiple grid acceleration and extensive rectorization and multi tasking. Several papers were produced during this effort including such titles as 'Multitasked embedded multigrid for three-dimensional flow simulation' and 'Multigrid approaches to the Euler equations'. An efficient algorithm designed to be used for Navier Stokes simulations of complex flows over complete configurations is described. The algorithm incorporates a number of elements, including an explicit three-dimensional flow solver, embedded mesh refinements, a model equation hierarchy ranging from the Euler equations through the full Navier-Stokes equations, multiple-grid convergence acceleration and extensive vectorization and multitasking for efficient execution on parallel processing supercomputers. Results are presented for a preliminary trial of the method on a problem representative of turbomachinery applications. Based on this performance data, it is estimated that a mature implementation of the algorithm will yield overall speedups ranging as high as 100.

UNCLASSIFIED REPORT

ABSTRACT: (U) The equations for the spatial and temporal modulations of the phase shift for slowly varying strongly nonlinear oscillators and dispersive waves have been determined for the first time. The effects of dissipative perturbations have been investigated for nonlinear oscillatory solutions of ordinary and partial differential equations (described by Klein-Gordon and Korteweg-de Vries type equations). The phase shift equations were derived using the method of multiple scales by evaluating the small perturbations to the exact action equation, a somewhat simpler technique than usual elimination of secular terms at an even higher order in the asymptotic expansion. It has been shown that, for dissipative perturbations, the frequency and action equations are valid to higher order and that their variations are only due to perturbations in the wave number and the averaged amplitude parameters. For second-order ordinary differential equations, the phase shift is determined from initial conditions in straight-forward manner since it was shown that there exists a new adiabatic invariant.

UNCLASSIFIED REPORT

ABSTRACT: (U) Automating rule strengths in expert systems is a way to alleviate the knowledge acquisition bottleneck. It is assumed that rules are fixed, except for the values of their strengths, which are computed or adjusted from initial values given by experts. A model of expert systems is proposed, in which rules have the form IF (P sub 1 & P sub 2 & . . . & P sub n) THEN C WITH ATTENUATION a, where P sub 1, P sub 2, . . . , P sub n, and C are weighted propositions, i.e., statements with a certainty factor (CF), and a, the strength of the rule, is a number between 0 and 1. To compute rule attenuations, two problem settings are considered. In the first, an oracle is given, that can provide the CFs of the conclusions of the entire rule-based system, given any assignment of certainty factors to the premises of the entire system (complete case). In the second, a fixed set of cases is available (incomplete case). A fast algorithm for synthesis in the complete case for simple rule bases is given both for MAX and probabilistic sum. In the incomplete case, the synthesis of attenuations is shown to be NP-Complete, even for very shallow rule bases with only two propositions in the premise of each rule, both for MAX and probabilistic sum. The refinement of attenuations from expert-given estimates is shown to be NP-Hard, no matter how close to the correct value the estimates are and how small an improvement towards the correct value is desired. ABSTRACT: (U) The most fundamental problem in the entire theory of oscillations is to describe the motion of a mass point, the tip mass, attached to a spring. Within the classical theory of particle mechanics, the spring is regarded as massless, so that it serves only to transmit a force to the tip mass. This force typically depends on the position and velocity of the tip mass in perhaps a nonlinear way. In this case, the motion is governed by an autonomous ordinary differential equation. On the other hand, if the spring has mass, then its motion as a continuum is coupled to that of the tip mass. If the spring has a nonlinear constitutive equation, then the analysis of the resulting motion, governed by partial differential equations, can be formidable indeed. This paper studies the motion of both tip mass and spring when the mass density of the spring is small and when its constitutive equation describes nonlinearly elastic and viscoelastic materials. Although these constitutive equations do not account for past history, if its nevertheless proven that in the formal limit as the spring's mass density goes to zero the equation for the tip mass is an ordinary differential equation for elastic springs, but is generally not so for viscoelastic springs.

ABSTRACT: (U) Numerical simulations of hypersonic shear flow, utilizing the full-time-dependent compressible flow Navier-Stokes equations, have been carried out to demonstrate the feasibility of exposing, computationally, the essential structure/physics of turbulent fluctuations in high speed flow. The geometry employed is one of interest to the U.S. Air Force in various applications, namely a right circular cylinder whose axis is aligned with the on-coming flow and around which the cylinder could be rotated. By simulating the flow along a cylinder of the infinite axial extent, an exceptionally quiet flow was established. Due to limitations of computational time, it was necessary to excite artificially this flowfield with periodic suction and blowing located well upstream of the observation plane. As a result, fluctuations in the flowfield entropy, vorticity and pressure were observed which revealed a distinct Mach number dependence. At hypersonic Mach numbers, the fluctuating entropy defined a second boundary layer edge, well beyond that of the vorticity but not propagating deep into the inviscid, flow, as was observed in both transonic and supersonic regimes.

ABSTRACT: (U) Our work has concentrated on developing a unifying framework, under the name UNITY, for studying problem-solving in parallel programming independent of specific architectural considerations. We have proposed a simple model of computation and a logic to reason about properties of such programs and have managed to study problems from a variety of problem areas. We have developed a number of transformations which are appropriate for implementations on a variety of architectures: sequential, asynchronous shared memory, distributed message passing, synchronous parallel with shared memory, systolic arrays, and VLSI chips. The diversity of the application areas and the architectures studied lends credence to our hypothesis that there is a UNITY to programming.

ABSTRACT: (U) A correspondence is established between a family of inverse scattering problems, including filter synthesis and seismic exploration, and a family of matrix factorization problems, including stochastic filtering, stability testing, partial/stochastic realization and model order reduction. This correspondence originates from the notion of energy conversation (i.e., losslessness), and it involves computational procedures whose signal-flow-graph representation is a lossless cascade network. Our analysis of recent results on efficient triangular factorization of Hermitian matrices indicates a possible extension of the network-theoretic notion of losslessness. (Reprints)

p247-283 1987.

ABSTRACT: (U) An investigation of an oblique shock wave/
laminar boundary layer interaction is presented. The Mach
number was 2.15, the Reynolds number was 100,000 and the
overall pressure ratio was 1.55. The interaction has been
demonstrated to be laminar and nominally two dimensional.
Experimental results include pressure distributions on
the plate in the attached and separated regions. The
numerical results have been obtained by solving the full
compressible Navier-Stokes equations with the implicit
approximate factorization algorithm by Beam & Warming
(1980). Comparison with experimental data shows good
agreement in terms of pressure distributions, positions
of separation and reattachment and velocity profiles.

UNCLASSIFIED REPORT

ABSTRACT: (U) The maintenance of large volatile
knowledge bases is the focus of this project. The
viewpoint from which the study is being conducted is that
of certain extensions of current logic programming
systems, primarily the so-called metalanguage systems in
which a logic programming language is amalgamated with a
portion of its metalanguage. Major thrusts of the work
include (1) study of the extent to which such
representation mechanisms as frames and semantic nets can
be logically treated (thus yielding a measure of
independence of representation for the rest of the work),
and (2) the use of the metalanguage facilities for the
maintenance of consistency and integrity under change and
other questions of analysis of the knowledge base.
Computer-based systems to aid human intelligence analysts
are instances of a generic class of systems known as
tracking systems. Such systems minimally consist of
knowledge base in which records representing the
analyst's concerns are stored. A useful organization of
such knowledge bases distinguishes between events and
event-lines. Events are relatively discrete in time, such
as signal reports or activity reports, while event-lines
are extended, continuous sequences of events. Events may
be thought of as discrete points, plotted on some event-
line. One maybe also impose a hierarchical structure
among event-lines with individual event-lines

ABSTRACT: (U) This paper proposes a notion of smooth
action on a manifold, and establishes a general
integrability result for certain associated distributions.
As corollaries, various classical and new results on
manifold structures of orbits are established, and the
main theorem on preservation of transitivity under
sampling is shown to be a simple consequence. One of the
basic results in control theory, states that, for
continuous time systems, each orbit (set accessible with
positive- and negative-time motions from a given starting
state) has a structural of immersed submanifold of the
state space. This structure is obtained, roughly, as
follows. Given any piecewise constant control steering a
state into the state x_i this control having switches at
times t_1, \dots, t_k , tangent vectors to the orbit
at x_i are obtained by taking perturbations of the t sub 1.
(More precisely, positive- and negative- time controlled
motions are used.) When phrased in terms of the
integrability of an associated distribution, this
generalizes classical theorems of Frobenius and Chow.

ABSTRACT: (U) In search for the best of n candidates,
two-stage procedures of the following type are in common
use. In a first stage, weak candidates are removed, and
the subset of promising candidates is then further
examined. At a second stage, the best of the candidates
in the subset is selected. In this article, optimization
is not aimed at the parameter with largest value but
rather at the best performance of the selected candidates
at Stage 2. Under a normal model, a new procedure based
on posterior percentiles is derived using a Bayes
approach, where nonsymmetric normal (proper and improper)
priors are applied. Comparisons are made with two other
procedures frequently used in selection decisions. The
three procedures and their performances are illustrated
with data from a recent recruitment process at a
Midwestern university. (Keywords: Screening; Scoring;

ABSTRACT: (U) When people use language spontaneously, they often do not adhere strictly to commonly accepted standards of grammaticality. The primary objective of this project is to develop flexible computer parsing techniques which can deal with the various kinds of ungrammaticalities that arise, both on the lexical and the phrase level. The progress towards this goal covered by this report includes: 1) The initial development of the FlexP flexible parser based on pattern-matching techniques; 2) Review of the initial design choices for FlexP in the light of this evaluation, leading to the formulation of the construction-specific approach to parsing, and its preliminary evaluation for applied natural language processing through the experimental parsers CASPAR and DYPAR; 3) Application of the construction-specific approach to flexible parsing to the parsing of an artificial command language in the parser for the Cousin command interface, a graceful interface for the Unix operating system; 4) Investigation of control structures that would allow the integration of multiple diverse parsing strategies into a single parsing system in an extensible manner; 5) Development of a taxonomy of grammatical deviations and recovery strategies for dealing with them; 6) Design and implementation of an initial version of MULTIPAR, the

ABSTRACT: (U) This paper is primarily concerned with computing first passage time statistics. In previous work a general reliability model was proposed in which system failures occur when either system wear-and-tear reaches some maximum permissible level (ie, a first passage occurs), or when some killing event happens (such killing events occur with rate $k(x)$ in state x). Under this model $w(x,t)$ satisfies a certain equation: It is possible to solve for $w(x,t)$ and related quantities with methods very similar to those presented here. In Section 2, algorithms for approximating $w(x,t)$ are obtained. In particular, the infinite spectral expansion for $w(x,t)$ is approximated by an n -term sub-expansion which matches the first $n-1$ moments. Section 2 concludes with some remarks about out preliminary computational experience. In Sections 3 and 4, methods are given for obtaining the eigenvalues and first passage moments, necessary for computing approximations to $w(x,t)$. In Section 5, computational issues related to calculating the moment generating function are considered. Section 6 and 7 include theoretical complements about first passage times. In particular, the moment generating function is shown to possess an interesting representation having exponential form. This exponential representation is related to asymptotic expansions used in analyzing perturbations of certain second-order differential equations.

ABSTRACT: (U) This document presents autoregressive (AR) and autoregressive moving average (ARMA) processes with bivariate exponential (BE) and bivariate geometric (BG) distributions. The theory of positive dependence is used to show that in various cases, the BEAR, BGAR, BEARMA, and BGARMA models consist of associated random variables. The authors discuss special cases of the BEAR and BGAR processes in which the bivariate processes are stationary and have well known bivariate exponential and geometric distributions. (Author)

ABSTRACT: (U) This volume is an executive summary of the research project on centrifugal and numerical modeling of buried structures subjected to static and dynamic loadings on the ground surface. Techniques were developed for testing model buried pipes in a geotechnical centrifuge. An impact generator was developed for applying an airblast loading on the centrifuge model. A dynamic stress gage was developed for measuring the stresses generated in the soil and acting on the buried pipe during the airblast loading. Finite element analyses were performed on the buried pipe experiments. Comparison between centrifuge test data and analytical results is used to validate the numerical analysis procedure.
Keywords: Soil-structure interaction; Centrifuge model testing; Static loading.

ABSTRACT: (U) This report covers activities of John R. Rice (PI) and associates since October 1984. The activity of Kai Huang is reported separately because it is being proposed that this grant be separated into two parts due to Kai Huang's change of position to the University of Southern California. The activities include (1) The completion and submission for publication of one technical paper on expert systems for partial differential equations, (2) The completion of one report on high level parallel languages for multiprocessors, (3) One manuscript to be presented at a conference in October 1985, (4) Three manuscripts in progress on the use of supercomputers, the use of distributed multiprocessor systems for PDEs and new numerical methods, (5) Considerable process in the analysis and high level restructuring of several important PDE algorithms for parallel execution. Independently of this grant, the investigators have just obtained a multiprocessor machine (the FLEX 32) which will greatly enhance the research program. (Author)

ABSTRACT: (U) Given that an item is of age t , the expected value of the random remaining life is called the mean residual life (MRL) at age t . We propose two new nonparametric classes of life distributions consisting of those with 'increasing initially, then decreasing mean residual life' (IDMRL). The IDMRL class models aging that is initially/beneficial, then adverse. The second class, decreasing, then increasing mean residual life (IDMRL), models aging that is initially adverse, then beneficial. We propose two testing procedures for H sub 0: constant MRL (i.e., exponentially) versus H sub 1: IDMRL, but not constant MRL (or H sub 1: DDMRL, but not constant MRL). The first testing procedure assumes the turning point, τ , from IDMRL to MRL is specified by the user or is known. The second procedure assumes knowledge of the proportion, ρ , of the population that dies at or before the turning point (knowledge of τ itself is not assumed).

SUPPLEMENTARY NOTE: Pub. in Jnl. of Quality Technology, v18 n3 p170-173 Jul 86.

ABSTRACT: (U) This paper discusses the effect of measurement errors in both variables when using the simple linear regression model. It is often stated that if the measurement error in x is small, then we can ignore this error and fit the model to data using ordinary least squares. There is some ambiguity in the statistical literature concerning the exact meaning of a small error. For example, Fraser and Smith (1981) state that if the measurement error variance in x is small relative to the variability of the true x 's, then 'errors in the x 's can be effectively ignored'. See Montgomery and Peck (1983) for a similar statement. Scheffe (1973) and Mandel (1984) argue for a second criterion, which may be informally summarized that the error in x should be small relative to (the standard deviation of the observed y about the line)/(slope of the line). We argue that for calibration experiments, both criteria are useful and important; the former for estimation of x given y , and the latter for the lengths of confidence intervals for x given y .

ABSTRACT: (U) The authors consider a K out of N system maintained by R repairmen, where the lifetime of the i sub th component is an exponentially distributed random variable with parameter μ_i . Repairmen are distinguishable, and the time it takes the r sub th repairmen to repair a failed component is an exponentially distributed random variable with parameter $\lambda_{r,i}$. Repaired components are as good as new and preemptions are allowed. It is shown that the policy which assigns the faster repairmen to the most reliable components is optimal with respect to several optimality criteria. The approach taken in establishing stochastic optimality with respect to the number of functioning components is of wide applicability to different classes of stochastic optimization problems. UNCLASSIFIED REPORT

ABSTRACT: (U) This paper examines the problem of estimating the state of a distributed finite-state Markov process consisting of several interacting finite-state systems each of whose transition probabilities are influenced by the states of the other processes. The observations on which the estimation procedure is based are continuous signals containing signatures indicative of the occurrence of particular events in the various finite-state systems. The problem of electrocardiogram analysis serves both as the primary motivation for this investigation and as the source of a case study we describe in the paper. The principal focus of the paper is on the development of an approach that overcomes the combinatorial explosion of truly optimal estimation algorithms. The authors accomplish this by constructing a systematic design methodology in which the resulting estimator consists of several interacting estimators, each focusing on a particular subprocess. Important questions addressed concern the way in which these estimators interact and the method each estimator uses to account in its own model for the influence of other subprocesses.

ABSTRACT: (U) Classical iterative schemes such as the Gauss-Seidel method and its variations constitute powerful tools for computing stationary distribution vectors for large-scale Markov process, such as those arising in queueing network analysis. The coefficient matrix A in these processes is a Q -matrix, i.e., a singular irreducible M -matrix with zero column sums and, unlike the nonsingular case, the classical iterations for A do not always converge. The purpose of this paper is to survey the recent literature and to analyze the behavior of these methods completely in terms of the graph structure of A . The results given here hold under somewhat weaker assumptions on A . Keywords: Markov chains, Queueing networks, Stochastic processes. (Author)

ABSTRACT: (U) The focus of this work was to study large volatile knowledge bases. The research involved developing extensions to logic programming systems in the form of a metalanguage, by studying to what extent frames and semantic nets could be employed. The management of consistency and integrity under change using a metalanguage was analyzed. This research produced a rule-based deductive programming language, called metaProlog, which enhances Prolog's ability to manipulate the databases themselves and to reason about them. This was accomplished by regarding databases (or theories) as first-class objects capable of being passed as arguments. Four papers were published under this grant, including Meta-kavek programming and knowledge representation and metaProlog: A metalevel extension to Prolog. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Details of the turbulence production process in turbulent boundary layers in the wall region have been clarified, especially the formation of the long streaky structure, and secondary hairpin vorticity. It appears that the outer region microscale coherent motion called a Typical eddy plays the dominant role in the process. Long time averaged statistics of the two point vorticity-vorticity correlations support the conditionally sampled data and interpretations. The typical eddy produces the long streaks along with the pockets, and one of the hairpins directly. Several other hairpins form from the evolution of the vorticity produced by the passage of the typical eddy over the wall. A model of the typical eddy/wall region interaction, i.e., a vortex ring/Stokes layer interaction, was investigated to see if it could reproduce all of the morphology. It was found that the model can produce all of the turbulent boundary layer features associated with production, including the long streaks. By using the model, we have gained new insights into the sensitivity of the production process. Relatively small differences in the convection velocity of the excitation eddies have been found to result in the difference between turbulent

ABSTRACT: (U) An algorithm for the Satisfiability problem is presented and its probabilistic behavior is analysed when combined with two other algorithms studied earlier. The analysis is based on an instance distribution which is parameterized to simulate a variety of sample characteristics. The algorithm dynamically assigns values to literals appearing in a given instance until a satisfying assignment is found or the algorithm gives up without determining whether or not a solution exists. It is shown that if n clauses are constructed independently from r boolean variables where the probability that a variable appears in a clause is a positive literal is p and as a negative literal is p then almost all randomly generated instances of satisfiability are solved in polynomial time under certain conditions. Thus the combined algorithm is very effective in the probabilistic sense on instances of SAT that have solutions.

ABSTRACT: (U) The Goose Bay HF radar is a sophisticated instrument capable of providing detailed information on very high latitude E and F region ionospheric electron density irregularities which act as a source of clutter on OTH radar systems. Through the use of two parallel phased array antennas, this instrument is able to image the location of these irregularities within a three-dimensional volume covering much of northeastern Canada and Greenland. It is also capable of following the temporal variability of these irregularities as well as determining unambiguously the Doppler shift and broadening of radar signals scattered by them. This paper presents initial results with a single phased array antenna which represent typical examples of the spatial intensity distribution of these irregularities at different local times. Examples are presented of Doppler spectra of the irregularities at different local times. Data of this type are of appreciable value in ascertaining the techniques that must be utilized to improve clutter mitigation on high latitude radar systems. (Reprints).

ABSTRACT: (U) The effects of orbital alignment on the calcium(4s5p 1p1) to calcium(4s5p 3Pj) electronic energy transfer process are determined for molecular collision partners, Hydrogen, Deuterium, Nitrogen, Oxygen, Carbon Monoxide, Carbon Dioxide, Methane, Ethane, and Sulfur hexafluoride. Most of the molecules exhibit negligible effects, except for H2(D2) and CO2, which show significant preferences for perpendicular and parallel initial orbital alignments, respectively. In the reverse transfer direction, hydrogen exhibits an even larger effect favoring the perpendicular laser polarization. Keywords: Laser molecules.

ABSTRACT: (U) Results on the numerical and analytic solution of implicit systems of differential equations and their application to circuit and control problems were developed. In particular, the first general algorithm for the linear time varying case was developed along with an analysis of how to apply it to certain control problems. New structure theorems provide insight on the convergence of backward formulas and guidelines for their use.

ABSTRACT: (U) A Transfer Matrix (TM) Analysis is formulated to predict the natural modes and frequencies of hoop-maypole type satellite antenna systems. Two directions of bending, axial extension/compression and torsion are represented as coupled by feed assemblies canting with respect to the mast, solar panels tilted out of the plane of the center structure and masses offset from the mast centerline. Shear deflections, large steady cable loads and large compressive loads are accounted for in appropriate members. Using properties chosen as representative of such structures, trends are predicted with variations in size and configuration for several simplified configurations; these include, (a) two-dimensional cable-suspended rigid bars on a flexible center body (mast), (b) T and H-shaped center body sub structures in two and three-dimensional vibrations and (c) cable-stiffened, planar polygonal hoop assemblies. IN the last of these cyclic symmetry had to be invoked to avoid numerical difficulties. Some general conclusions are drawn regarding the free vibrations of such structures. The TM approach is seen as a viable alternative to FEM analyses, when structures are encountered which have major substructures with one dimension longer than its others. Full use of the TM analysis for hoop-maypole type structures must await a reformulation in which cyclic symmetry can be invoked, as in the plane hoop cases.

ABSTRACT: (U) From time of the inception of this work, it became clear at a relatively early stage that the USC MBE facility required major effort and investment to be able to grow reliable samples. In an effort to achieve this aim, the principal investigator was forced to take responsibility of the MBE growth as well - a situation not originally anticipated. Accordingly, major effort was spent making the USC MBE machine operational and putting in place basic support facilities (such as substrate cleaning and preparation). The situation with regard to the MBE machine thus, unfortunately, deprived us of appropriate GaAs/Al GaI-xAs samples to be able to proceed with certain experiments. We did, however, grow a few GaAs/Alx GaI-xAs/GaAs tunneling structures and carried on fabricated into actual tunnel structures, and carried on Fowler-Norheim resonance tunneling experiments at JPL. The results indicated that the interfacial quality of these structures were rather poor.

ABSTRACT: (U) The purpose of this paper is to discuss some characteristics of the typical cluster size for the self-matching 2-dimensional percolation models. For simplicity the author only describes his results for the site percolation model on double Z squared and leaves the task of extending this discussion to general models to the readers. Let us now introduce the 2-dim site percolation model. Let p sub p denote the probability measure under which all sites of the lattice double Z squared are independently occupied (non-occupied) with probability p (respectively $1-p$). It is said that x is connected to y if there is a nearest neighbor path over occupied sites connecting x and y . Let W sub $0 = \{x$ epsilon double Z squared: 0 approaches limit of x : the cluster of occupied sites connected to 0 . This paper is devoted to the study of certain special properties of the typical cluster size about the critical point p sub $c = \inf\{p : p$ sub p (0 approaches limit of infinity > 0).

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on Information Theory, VIT-32 n4 p496-512 Jul 86.

ABSTRACT: (U) While delta modulation (DM) simply compares the current predictive estimate of the input with the current sample, delayed delta modulation (DDM) also compares with the upcoming sample so as to detect and anticipate slope overloading. Since this future sample must be available before the present output is determined and the estimate updated, delay is introduced at the encoding. The performance of DDM with perfect integration and step-function reconstruction is analyzed for each of three random input signals. The stochastic stability of the system is established. For a discrete time, independent and identically distributed input, the (limiting) joint distribution of input and output is derived, and the (asymptotic) mean-square sample point error $mse(SPE)$ is computed when the input is Gaussian. For a Wiener input, the joint distribution of the sample point and prediction errors is derived, and $mse(SP)$ and the time-averaged $mse(mse(TA))$ are computed. For a stationary first-order Gauss-Markov input, the joint distribution of input and output is derived and $mse(SP)$ and $mse(TA)$ computed. Graphs of the mse 's illustrate the improvement attainable by using DDM instead of DM. With optimal setting of parameters, $mse(SP)(mse(TA))$ is

ABSTRACT: (U) The problem of calculating the two-
terminal reliability of a network having edges that fail
randomly and independently is known to be NP-hard, even
in the case of directed acyclic networks. This paper
discusses an iterative technique that provides at each
iteration both upper and lower bounds on the exact
reliability value. These bounds are shown to converge to
the exact answer for the case of acyclic networks.
Computational results indicate that for certain classes
of graphs these bounds converge rapidly and provide
excellent approximations to the true network reliability.

ABSTRACT: (U) Let $(\text{sub } 1), \dots, (\text{sub } n), \dots$ be i.i.d.
observations of a random vector (X, Y) where Y is one-
dimensional and X may be multi-dimensional. Suppose that
the regression of Y to X , in some sense, is a linear
function $\alpha \text{ sub } 0 + \beta \text{ sub } 0$. It is desired to
estimate the unknown parameters $\alpha \text{ sub } 0, \beta \text{ sub } 0$,
using the observations $(\text{sub } 1), \dots, (\text{sub } n)$. A much
discussed class of estimates is the so-called M-estimate,
which takes the solution of a certain minimization
problem as the estimator. Here ρ is a properly selected
function defined over $R^p = (\text{infinity})$. (Keywords: linear
models).

ABSTRACT: (U) This grant consisted of two parts: the installation of a Local Area Network and the installation of a network of four graphics workstations. The Local Area Network (LAN) was operational in June of 1986. The department has about 25 terminals connected to the network. Most of the terminals are located in the offices of the faculty and graduate students, with a few in a joint-use equipment room. The response is that this has greatly improved the departmental computing environment. In addition, 7 faculty members have been given microcomputers by the university of New Mexico and these have been connected to the LAN. This configuration seems to provide an excellent computing environment. Some of the faculty have found that current microcomputers are too small and have too little software, so the University will hopefully replace some of these with more powerful micros, which will also be connected to the LAN. This network has and will continue to have a substantial impact on the research and teaching in the department. However, there is no easy way to verify this except through the informal reports of the people using the system. The network of workstations was operational in August of 1985. The network of workstation consists of four Sun-2/180 minicomputers; each has a tape and disk drive. These are connected via an ethernet, which is

ABSTRACT: (U) Compositionally diphasic xerogels. These materials are very intimate mixtures composed of two solid phases each on the order of 10-20 nm. The two phases are only different in composition. Using the mullite (3Al₂O₃SiO₂) system as the prototype model, we have shown that the compositionally diphasic materials sinter to a much lower temperature than the single phase gels. Such sintering of compositionally diphasic gels at much lower temperatures may be attributed, at least in part, to the heat of reaction of the two discrete phases at the sintering temperature. This notion was extended to other systems such as Al₂TiO₅, ZrSiO₄, ThSiO₄ and Mg₂Al₄SiO₁₈. Results to date on the Al₂TiO₅, ZrSiO₄ and ThSiO₄ systems do not show significant improvements in densification behavior although the use of diphasic gels led to a lowering in the crystallization temperatures of ZrSiO₄, ThSiO₄, etc. The diphasic Mg₂Al₄SiO₁₈ system exhibits metastable melting which could be used for enhanced densification of this low-expansion ceramic. Using the diphasic approach, we have also prepared translucent ultra-low expansion titania-silica glasses with 0 to 10% TiO₂. The coefficients of thermal expansion are intermediate between those of fused silica and a commercial titania-silica glass. The glass with 7.2% TiO₂ exhibited a zero thermal expansion coefficient at 150-210

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper defines Y sub 0 to be a geometric convolution of X if Y sub 0 is the sum of N sub 0 i.i.d. random variables distributed as X , where N sub 0 is geometrically distributed and independent of X . It is known that if X is non-negative with finite second moment then as p approaches limit of 0, Y sub 0/EY sub 0 converges in distribution to an exponential distribution with mean 1. Derive an upper bound for $d(Y$ sub 0), the distance between Y sub 0 and an exponential with mean Y sub 0, namely for $0 < p < \text{or} = 1/2$, $d(\text{sub } 0) < \text{or} = cp$ where $c = sq \text{ ex/sq } (ex)$. This bound is asymptotically (p approaches limit of 0) tight.

IDENTIFIERS: (U) Error bounds, *Geometric convolutions.

ABSTRACT: (U) A unified theory of secondary instability in wall-bound shear flows has been developed. This theory rests on Floquet systems of stability equations and permits classification and quantitative analysis of different modes of secondary instability in the three-dimensional stage of laminar-turbulent transition. The catalogue of solutions is consistent with observations and predicts other phenomena that have not been identified in experiments. The theoretical results have been used to reproduce patterns in flow visualizations by computer animation. Analysis of the energy balance has shown a feedback loop between mean flow, two-dimensional, and three-dimensional disturbances that is considered key to the process of self-sustained transition. Various techniques have been developed to investigate details of the nonlinear three-dimensional processes involved in this feedback loop. Keywords: Boundary layer, Stability, Transition.

DESCRIPTORS: (U) *BOUNDARY LAYER FLOW, *BOUNDARY LAYER TRANSITION, BALANCE, BOUNDARY LAYER, CATALOGS, ENERGY, EQUATIONS, FEEDBACK, FLOW, FLOW VISUALIZATION, LAMINAR FLOW, LOOPS, MEAN, NONLINEAR SYSTEMS, QUANTITATIVE ANALYSIS, SECONDARY, SOLUTIONS(GENERAL), STABILITY, STRUCTURES, THEORY, THREE DIMENSIONAL, TRANSITIONS.

UNCLASSIFIED REPORT

ABSTRACT: (U) A block-structured solution scheme was developed for the solution of three-dimensional Euler equations around complex geometric configurations. The overall effort included the development of a block-structured solution of both potential and Euler equations. The flow field around a complex geometry is divided into blocks with simple geometries. The computational grid is generated individually for each of the blocks, either potential of Euler equations are solved independently using the finite element method. The normal mass and entropy fluxes are balanced between the blocks iteratively by using a relaxation scheme. This scheme is implemented on large computers (Cray and IBM) using parallel processing capabilities such as asynchronous I/O and several Cpu's. Keywords: Transonic flow; Three dimensional; Airfoils; F-16 Aircraft. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) In this Phase I study funded under the Small Business Innovation Research (SBIR) program, statistical methods are developed using the predictive inference and entropy approach. Previous recent research has derived entropy as the natural measure of model approximation error from the fundamental statistical principles of sufficiency and repeated sampling. In this study, the areas of nonnested multiple comparison, multivariable time series analysis, adaptive time series analysis of changing processes, and optimal small sample inference are investigated. Constrained maximum likelihood methods are developed for general nonnested multiple comparison. For the asymptotic optimality of these methods, a condition on the Fisher information and Hessian matrices must be satisfied. Applying these results to multivariate time series analysis, lower bounds are derived for the achievable accuracy of the estimated transfer function and spectral matrices. Markov and canonical variate analysis (CVA) provide a means of numerically and statistically stable model fitting of multivariable time series, and these methods provide a basis for modeling fitting time varying models of changing processes.

UNCLASSIFIED REPORT

ABSTRACT: (U) The purpose of obtaining the gene of Adenosinediphosphoribosyl Transferase (ADPRT) is: 1) the complete amino acid sequence of this large protein is best determined from the DNA sequence of the gene, 2) isolation of the gene provides gene probes that permit location and quantitation of the gene within genomic DNA, and 3) a variety of biological experiments at the cellular level requires specific gene probes. The DNA-associating enzyme, adenosinediphosphoribosyl transferase, has been isolated from calf thymus by selective precipitation with a solution of dihydroxy-Reactive Red 120, followed by extraction of the enzyme from the precipitate with 2 M KCl and an on-line train of three successive column chromatographic steps, including a final 3-aminobenzamide-Sepharose-4B affinity chromatography. The method yields 8-9 mg of more than 95% homogeneous enzyme protein per kg starting material and requires about 3 working days. This dye precipitation method is distinct from affinity precipitation, since it involves the binding of the dye to both nonspecific sites and the substrate- and DNA-site of the transferase as indicated by enzyme inhibition by dihydroxy Reactive red 120 at both enzyme sites.

UNCLASSIFIED REPORT

ABSTRACT: (U) This project yielded the following significant new discoveries and findings about solar magnetic fields: The majority of magnetic flux on the sun is observed to disappear when magnetic fields of one polarity migrate into or develop in juxtaposition with fields of opposite polarity. The cancellation of magnetic fields can be interpreted as: (a) submergence (b) reconnection or (c) dissipation (annihilation) of magnetic fields. Large-scale filaments are observed to form in the chromosphere immediately above the boundaries between areas of network magnetic field of opposite polarity where network cancellation occurs. Small-scale filaments develop in association with small-scale cancelling magnetic fields at the rate of hundreds per day. Magnetic fields associated with large-scale solar convection cells, known as intranetwork magnetic fields, can be detected everywhere on the visible disk of the sun by using the videomagnetograph to integrate successive, 1/15 sec. magnetic field images for intervals of 1 to 10 minutes. The intranetwork field appear to be a few seconds of arc in diameter, and have field strengths of the order of a few Gauss to tens of Gauss. The intranetwork fields appear to originate at the centers of supergranules and flow to the boundaries of the cells in approximately radial patterns.

UNCLASSIFIED REPORT

ABSTRACT: (U) The structure of an incompressible turbulent boundary layer subjected to a strong adverse pressure gradient is studied by means of an asymptotic analysis of the Reynolds time-averaged equations. Limit-process expansions developed in the limit of large Reynolds number reveal a relatively thick nondefect layer in the outer region of the boundary layer near the exterior inviscid flow, and a relatively thin layer near the wall. To leading orders of approximation, the momentum balance involves convection, pressure gradient, and turbulent stress in the outer layer, and pressure gradient, and turbulent and viscous stresses in the inner layer. The asymptotic expansions for these two layers are matched in an arbitrary intermediate region, wherein the streamwise velocity has a square-root dependence and the Reynolds stress has a corresponding linear dependence on the normal coordinate. The leading-order approximations for the outer and inner layers give rise to similarity formulations, from which appropriate similarity formulations for the distinguished intermediate layer have been identified and developed. These latter formulations are employed to analyze available experimental data.

ABSTRACT: (U) Of the molecules measured with EFISH there is a striking constancy of their microbeta products and even the more approximate beta's themselves. These molecules are all nitrobenzene derivatives and the observation could be made that the magnitude of beta is more or less tied to this conjugated portion of the molecules. Comparison of the power data with the molecular hyperpolarizabilities illustrates that a study of powder response tells essentially nothing whatever about molecular properties. Attention should be directed to crystal studies in the search for materials destined for application to the processing of weak optical signals. The dependence of molecular polarizability on concentration in some solvents for some solutes at very low concentrations has not been clearly seen before. These measurements were all made on solutions of less than 1 molecular percent and so solute-solute interaction almost certainly is absent.

ABSTRACT: (U) This document describes the structure of most of these processes and discuss some of their basic properties. The coverage does not include several important topics requiring lengthy mathematical development (e.g. martingale theory of point processes, general Palm probabilities, and ergodic and spectral analysis of stationary processes). The emphasis will be one presenting tools for modeling stochastic systems rather than on applications of the tools. Although the theory of point processes is intimately connected with the subject of measure and integration (a point process is a random counting measure). The author focused on results that can be understood without a deep knowledge of measure theory. On the other hand, the presentation will be rigorous and at the level of the applied probability literature that one would encounter in studying point processes. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Ambient and elevated temperature tensile and creep response, and microstructural stability of a powder processed Al-Fe-Ce alloy have been evaluated. Gas atomized Al-Fe-C was mechanically alloyed (MA) to give a volume fraction of dispersoids of about 0.23. The powder was could isostatically pressed in aluminum cans, outgassed and hot extruded to full density. Consistent with improved microstructural stability at elevated temperatures, the MA material is stronger and more creep resistant than the non-MA material. These improvements are attributed to the presence of fine scale oxides and carbides distributed uniformly throughout the structure, and which are introduced during MA; the dispersion inhibits coarsening, recovery and recrystallization. Non-MA Al-Fe-Ce is stronger than non-MA Al-Fe-Ni at all temperatures but it has limited ductility. Qualitatively, the effect of MA on Al-Fe-Ce is similar to that in Al-Fe-Ni. These results suggest that Ce alters the transformation characteristics of Al-Fe and/or that Ce diffuses more slowly than Ni in Al, in the presence of Fe.

UNCLASSIFIED REPORT

ABSTRACT: (U) Unified explicit analytical solutions for the (non-axisymmetric) first and second boundary value problems of elasticity theory for a spheroidal cavity embedded in a transversely isotropic medium are presented. The analysis is based upon solutions of the homogeneous displacement equations of equilibrium in terms of three quasi-harmonic potential functions, each of which is harmonic in a space different from the physical space. Thus, three spheroidal coordinate systems with different metric scales (one for each potential) are introduced such that the three coordinate systems coincide on the spheroidal cavity. These potential functions are taken in a unique combination of the associated Legendre functions of the first and second kind. Extensive numerical data are obtained for the stress concentration factors associated with axisymmetric and non-axisymmetric problems for a variety of materials. The effect of anisotropy on the stress concentration factor is discussed in much greater detail than has been previously available in the literature.

DESCRIPTORS: (U) *STRESS CONCENTRATION, COMPOSITE MATERIALS, SPHERES, ANISOTROPY, BOUNDARY VALUE PROBLEMS, CAVITIES, LEGENDRE FUNCTIONS, THREE DIMENSIONAL.

UNCLASSIFIED REPORT

ABSTRACT: (U) Transfer matrices and joint coupling matrices are used to compute natural frequencies of vibration of a five-bay planar lattice structure. The method of analysis may be applied to general two and three-dimensional lattices. The necessary numerical computations may be performed easily with a personal computer. Numerical results for the first twenty-five nonzero natural frequencies of the five-bay planar lattice structure are given for the case when the members of the lattice are modeled as Bernoulli-Euler beams, and for the case when the members of the lattice are modeled as Timoshenko beams. The maximum difference in the computed natural frequencies of the two models occurs in the twenty-fifth mode and is less than one-half of one percent. The natural frequencies obtained here agree within six percent with the natural frequencies obtained in a previous analysis using a finite element method and an experimental modal analysis.

DESCRIPTORS: (U) *STRUCTURAL MEMBERS, *LATTICE DYNAMICS, VIBRATION, TRANSFER FUNCTIONS, MATRICES(MATHEMATICS), SPACE SYSTEMS, RESONANT FREQUENCY, FINITE ELEMENT ANALYSIS, TIMOSHENKO BEAM.

IDENTIFIERS: (U) Bernoulli Euler beam, PE61102F.

UNCLASSIFIED REPORT

ABSTRACT: (U) The model ionosphere was developed that is coupled to a magnetospheric model for investigating time dependent behavior of the Polar F-region ionosphere in response to varying interplanetary magnetic field (IMF) configurations. The numerical ionospheric model covers a latitude range from 50 to 90 degrees and an altitude range of 150 to 800 KM. The purpose of the magnetospheric model is to define the location and geometry of the polar cap, which is defined as the region of open field lines. The polar cap configuration has been coupled to a model electric field pattern that in turn may vary in size and strength in response to the IMF. The ionosphere model assumes only oxygen ions; the ion density is solved vertically along many magnetic field lines as they move horizontally under the influence of the large-scale convective electric fields. The lower boundary is defined by the local chemistry and the upper boundary condition has been set by applying an outward flux of ions appropriate for open field line conditions. The model has been used to illustrate ionospheric behavior during geomagnetic storms conditions. Future model applications may include ionospheric prediction using IMF inputs improved understanding of polar ionization structures.

ABSTRACT: (U) The first phase of this program was investigation of triquinoyl hydrate (hexaketocyclohexane octahydrate, C₆H₁₆O₁₄) which is formed when certain cyclohexane derivatives are treated with cold nitric acid. This ketone hydrate has now been characterized by measurements of its elemental composition, x-ray diffraction pattern, density, infrared and Raman spectrum, carbon thirteen NMR pattern, ultraviolet absorption and fluorescence spectra, ion chromatogram, potentiometric titration curve, solubility, rate of weight loss at several temperatures, heat of decomposition and of combustion, and reactivity toward several different nucleophiles, reducing agents and oxidizing agents. The ketone hydrate is an unusually dense, tightly hydrogen-bonded, acidic, crystalline material which in solution rapidly undergoes dehydration, disproportionation and ring-opening reactions. It may be regarded as a graphite oxide (graphitic acid) having the maximum oxygen-to-carbon ratio.

ABSTRACT: (U) Second order turbulence closure models for conditional moments and the intermittency factor were developed. Methods for the treatment of turbulent/non-turbulent and other scalar interfaces were applied to the plane mixing layer and round jet. Multiscale closure models based on the dissipation rate were developed and applied to homogeneous turbulence and the plane jet. Scalar transport was investigated using the separation probability of clusters of particles and numerical solutions based on stochastic simulation techniques. A direct extension of conditional closure to velocity-scalar pdf equations was also developed.

ABSTRACT: (U) Summary of major research findings in three topical areas: 1) traveling wave concepts in the dynamics and control of Large Space Structures, 2) passive damping in Large Space Structures Applications, and 3) active control of rigid and flexible Manipulator Arms. The traveling wave concepts for characterizing the dynamics of flexible structures have introduced an alternative to modal synthesis and established a basis for the development of new controls algorithms. Passive damping studies identified various types of damping mechanisms including thermoelastic, and electromagnetic, and quantified their relative contributions. The active control studies generated a number of algorithms and control strategies and demonstration applications.

ABSTRACT: (U) This paper is devoted to an analytical
comparison of the various elliptic partial-differential-
equation (PDE) models which are in current use for grid
generation. These comparisons, particularly between the
equations from the Laplace-Poisson system and the
expressions from a Gaussian approach, have yielded useful
expressions connecting the 3D Laplacians and the surface
Beltrami. This effort has specifically been successful
when the transverse coordinate leaving the surface is
orthogonal to the surface. Equations which are derivable
from Cartesian-type Poisson equations and those obtained
by using the variational principle in surface coordinates
have also been considered. (Author)

ABSTRACT: (U) This document considers a parameterized
family of two-stage stochastic control problems with
nonclassical information patterns, which includes the
well-known 1988 counterexample of Witsenhausen. It is
shown that whenever the performance index does not
contain a product term between the decision variables,
the optimal solution is linear in the observation
variables. The parameter space can be partitioned into
two regions in one of which the optimal solution is
linear, whereas in the other it is inherently nonlinear.
Extensive computations using two-point piecewise constant
policies and linear plus piecewise constant policies
provide numerical evidence that nonlinear policies may
indeed outperform linear policies when the product term
is present. (Author)

ABSTRACT: (U) Two-dimensional imaging of CO concentration in combustion gases is demonstrated using two-photon-excited planar laser-induced fluorescence. A quantitative model is presented for the simultaneous two-photon excitation of several rotational transitions of the B to A system and the subsequent visible fluorescence (F to A). The model is verified by comparison of predicted and measured excitation spectra and of temperature-corrected relative fluorescence measurements to standard probe measurements of the center line CO distribution in a CO-air diffusion flame. In addition, CO imaging experiments in a premixed methane-air flame indicate the production of C2 by laser photodissociation of acetylene.

ABSTRACT: (U) The classical algorithms of Schur and Levinson are efficient procedures to obtain the triangular factorization of, respectively, a Hermitian Toeplitz matrix and its inverse. Extensions of the Schur algorithms to Hermitian Quasi-Toeplitz (Q-T) matrices (matrices with certain hidden Toeplitz structure) and the Levinson algorithm to admissible (a sub-class of) Q-T matrices are also known. This paper extends these Schur and Levinson algorithms to non-Hermitian Q-T matrices. The fast algorithms for non-Hermitian Q-T matrices are shown to be associated with two discrete transmission lines which reduce to the familiar single lattice in the Hermitian case.

ABSTRACT: (U) Planar laser-induced fluorescence of O₂ has been used to acquire quantitative, instantaneous two-dimensional images of temperature in heated air flows. O₂ is excited by using a broadband ArF excimer laser at 193 nm, and the resultant fluorescence signal is converted to temperature by using a theoretical calculation of the dependence of the fluorescence on temperature. This calculation has been confirmed experimentally, and validating data are presented.

ABSTRACT: (U) The important problem of Adaptive Line Enhancing (ALE) is addressed in this paper. Its solution involves an Adaptive Notch Filter (ANF) proposed in references using a minimal parameter constrained infinite impulse response (IIR) model in conjunction with the Recursive Prediction Error Method (RPEM). A Fast Transversal Filter (FTF) algorithm for the adaptive RLS-type updating of the linear phase filter is presented. (Author)

ABSTRACT: (U) The class of new better than used in expectation life distributions is shown to be closed under the formation of parallel systems with independent and identically distributed components. The class of differentiable life distributions with decreasing mean residual life is also proved to have the same closure property.

ABSTRACT: (U) This project has initiated an ongoing study of singular stochastic control problems of the finite-fuel type, and their relations to questions of optimal stopping. These problems are studied here mainly by analytical techniques; they lead to explicitly solvable free boundary problems, and to simpler questions in stochastic optimization, such as families of optimal stopping problems, and singular control with unlimited fuel.

ABSTRACT: (U) Motivated by the results on steady-state periodic tracking, a continuous-time nonzero set point regulation problem is considered which involves 1) noisy and nonnoisy measurements, 2) weighted and unweighted controls, 3) correlated plant/measurement noise and cross weighting, 4) nonzero-mean disturbances, and 5) state-control- and measurement-dependent white noise. It is shown that in the absence of multiplicative disturbances the closed-loop control can be designed independently of the open-loop control. The results are obtained without using the overtaking criterion.

ABSTRACT: (U) This project is intended to combine:
pattern recognition, image understanding and artificial
intelligence techniques for space-based image processing
as well as: optical and digital processing methods.
Optical feature extraction and sub-pixel target detection
and tracking results are summarized. Scene representation
and modeling work using: probabilistic graph matching,
multiple resolution rotation-invariant operators and
texture analysis are detailed. Image understanding include
techniques for 3D scene interpretation discussed include
2D image-level methods (using features such as edges,
lines and corners) and 3D scene-level methods. New
dynamic programming, stereo image and model building
results are included.

ABSTRACT: (U) The author considers an undirected network G with node set V and arc set $E = (1, \dots, n)$ where arcs fall randomly and independently. Let T be a subset of V and let M sub k denote the number of ways that all the nodes of T are connected (T -connectivity) with exactly k operating arcs and $n - k$ failed arcs. This paper describes a sampling plan for estimating (M sub k) and linear functions of these parameters, including the T -connectedness reliability function $g(p)$ for common failure probability $1 - p$.

ABSTRACT: (U) Steady-state linear laser induced fluorescence (LIF) has been used to investigate internal energy redistribution rates in A2 delta $v' = 0$ CH in a low pressure oxy-acetylene flame. By obtaining rotationally resolved spectra as a function of pressure the branching ratio, defined as the ratio of rotational transfer (R) out of the laser excited state divided by the electronic quenching rate (Q), was measured for a variety of flame conditions. For a stoichiometric 1800K flame and $K' = 6$ excitation $R/Q = 3.6 \pm 0.5$. The branching ratio was also found to increase with K' and decrease with equivalence ratio. In addition, for $K' = 6$ excitation, a value of the electronic quenching cross section of $5.4 \pm 0.3 \times 10^{-16}$ cm² was obtained.

SUPPLEMENTARY NOTE: Pub. in Stochastic Processes and Their Applications, v24 p1-18 1987.

SUPPLEMENTARY NOTE: Prepared in cooperation with Washington State Univ.

ABSTRACT: (U) Spectral necessary and sufficient conditions are derived for stationary symmetric stable processes to be metrically transitive and mixing. Then consider some important classes of stationary stable processes: Sub-Gaussian stationary processes and stationary stable processes with a harmonic spectral representation are never metrically transitive, the latter in sharp contrast with the Gaussian case. Stable processes with a harmonic spectral representation satisfy a strong law of large numbers even though they are not generally stationary. For doubly stationary stable processes, sufficient conditions are derived for metric transitivity and mixing, and necessary and sufficient conditions for a strong law of large numbers.

ABSTRACT: (U) The authors introduce the problem with an example. How should we design an experiment to compare 4 test treatments with a control, using 18 experimental units? As a statistical question we will not be able to answer it unless it is asked in a more precise manner. To begin with we need to postulate a model for the response observed upon application of a treatment, test treatment or control, to an experimental unit. This paper shall consider three possible models: 1) 0-way elimination of heterogeneity model in which all experimental units are homogeneous before application of treatments; 2) 1-way elimination of heterogeneity model in which experimental units can be divided into several homogeneous blocks; and 3) 2-way elimination of heterogeneity model in which the experimental units can be conceptually arranged according to rows and columns.

ABSTRACT: (U) Quadtree representation of matrices offers a homogeneous representation for both sparse and dense matrices, with advantages for processing on multiprocessors. This paper offers exact values for the average depth and on the number of nodes in this representation of some familiar patterned matrices: symmetric, triangular, and banded. It similarly measures three permutation matrices as comparative examples of non-dense, unpatterned matrices. Those results are exact values for the shuffle and bit-reversal permutations raised by the fast Fourier transform, as well as tight bounds on the expected values from purely random permutations. Two different measures for density and for sparsity are proposed from these values, and a simple analysis of quadtree matrix addition is given as an illustration of these measures. (Author)

ABSTRACT: (U) The N2-sila-acyl complex cp-C13Ta(N2-COSiMe3) (CP-n5-C5Me5) (1) reacts rapidly with diphenyldiazomethane to form cp-C13Ta(OC(SiMe3)NNCPh2) (2), the first characterized product of reaction between an N2-acyl compound and a diazoalkane.

ABSTRACT: (U) This paper demonstrates the equivalence of the Euler and the Lagrangian equations of gas dynamics in one space dimension for weak solutions which are bounded and measurable in Eulerian coordinates. The precise hypotheses include all known global solutions on $R \times R^+$. In particular, solutions containing vacuum states (zero mass density) are included. Furthermore, there is a one-to-one corresponding admissibility criteria are equivalent. In the presence of a vacuum, the definition of weak solution for the Lagrangian equations must be strengthened to admit test functions which are discontinuous at the vacuum. As an application, we translate a large-date existence result of Diperna for the Euler equations for isentropic gas dynamics into a similar theorem for the Lagrangian equations.

Scaling of Cellular Automaton Hydrodynamics; and
Renormalization Group Analysis of Turbulence. I. Basic
Theory.

DESCRIPTORS: (U) *TURBULENCE, *DIGITAL SIMULATION,
*EDDIES(FLUID MECHANICS), *REYNOLDS NUMBER, *SHEAR STRESSES,
*AUTOMATA, *TRANSPORT PROPERTIES, *SCALING FACTORS,
*GROUPS(MATHEMATICS), *HYDRODYNAMICS.

IDENTIFIERS: (U) Cellular automata, WJAFOSR2307A2,
PE61102F.

ABSTRACT: (U) For sequential decision processes, we
consider the problem of obtaining the min-max strategy
which minimizes the worst case performance. This is a
game against nature, attempts to maximize it. It is
apparently a folk theorem that such a min-max strategy
can be obtained by means of a dynamic programming like
recursion, even though we have not seen any general proof
of this, applicable to stochastic systems, which does not
rely on the existence of a saddle point. We prove this
theorem and also examine the precise roles of the
strategy sets allowed to the minimizer and the maximizer
in determining the upper value of the game. Improvements
in the results for the case of deterministic systems and
generalizations to continuous time systems are indicated.

DESCRIPTORS: (U) *MINIMAX TECHNIQUE, *DYNAMIC PROGRAMMING,
*OPTIMIZATION, *STOCHASTIC PROCESSES, *CONTROL SYSTEMS,
*REPRINTS.

IDENTIFIERS: (U) Markov chains.

UNCLASSIFIED REPORT

ABSTRACT: (U) Hierarchical models are important in Bayesian prediction because they enable the use of collateral data from related risks with exchangeable parameters. The classical normal-normal model with random means show clearly how the linear predictive mean for a single risk is improved by the availability of cohort data. However, this model has the disadvantage that the predictive density is homoscedastic, that is, the posterior variance depends only on the design (number of risks and number of samples). In most applications, one would assume that the variance also depended upon the data values. One can, of course, change the variances at each level into random parameters, but this modifies the predictive mean formulae and leads to messy results in general. In the course of examining approximations to r predictive variances, the author has found an extended normal model with variances that are quadratic in the data, and with the additional advantage that the linear mean formulae are unchanged.
